Abstract

The Zambian economy has grown relatively fast over the last decade up to the current global financial crisis. This paper discusses the challenge of using these growing resources effectively to improve the welfare of the population and to reduce poverty. The poverty head count index is found to have declined from 1998 to 2004 by about 5.4 percentage points. This change can be decomposed into a 6.6 percentage point reduction due to growth and a 1.2 percentage point increase due to inequality change.

Since poverty is most severe in the rural areas it is important to make agriculture more efficient by improving roads and electricity, extension services and education. Our discussion further highlights the need to improve tax revenue collection and efficiency in realising budget expenditure plans. An important reform to undertake would be to change the budget cycle. The private sector development strategy should make the country a more attractive destination for private investors by creating a better business environment and infrastructure. The country also needs a new trading arrangement with the EU. Poverty relevant social services such as health and education remain vital. The health sector needs to be strengthened both because it has an immediate effect on welfare and because it helps build and protect human capital that is essential for long-term growth. Also social protection might have a role to play. It might be possible to use schools for channelling resources to the poor. Finally, improved governance helps all other measures to become more efficient.

Keywords: Zambia, poverty estimates, economic policy, budget, private sector, social services.

Renewed Growth and Poverty Reduction in Zambia

1. Introduction

The Zambian economy has been growing relatively fast over the last decade, and per capita incomes have been increasing after a long period of stagnation or decline. This positive trend is obviously going to be affected by the current global financial crisis, but our analysis is restricted to the period before the crisis. During that period Zambia experienced strong improvements in terms of trade, but realistic observers always expected copper prices to decline over the medium term. In any event the country faces the challenge of using resources effectively to improve the welfare of the population and reduce poverty. We discuss public sector effectiveness (including tax revenue collection, financial management, transparency, accountability, education and health services), private sector development and agriculture. We analyze empirically the incidence of growth 1998-2004 on both urban and rural households.

There is a need to strengthen the analysis of the poverty implications of growth in Zambia. It is particularly pertinent since the experience from resource rich African countries is that incomes from natural resources tend to be distributed inequitably (Ndulu and O’Connell, 2008). It has also been hard to sustain growth accelerations in African economies. Between 1994 and 2005 GDP per capita in Sub-Saharan Africa excluding South Africa (“Africa” from here on) has grown by on average 2.1 % per year, which is slightly higher than during the last period of good African growth 1964-74. The policy challenge for Zambia is thus to use this opportunity to generate broad-based growth with effective poverty reduction as the result.

Zambia is in the process of implementing its Fifth National Development Plan (FNDP) 2006-2010, which is to guide policy formulation and implementation over the plan
The theme of the plan is broad-based wealth creation through citizen participation and technological advancement. A major weakness in previous plans has been their poor implementation due to poor resource forecasts, weak institutional arrangements and weak monitoring. It is hoped that new public expenditure management and accountability systems will improve the implementation.

In the FNDP (2006, p.1) it is noted that “wealth creation through sustained economic growth constitutes the most important poverty reduction”. It is thus acknowledged that sustained and significant poverty reduction cannot be achieved unless the economy grows. It is also pointed out in the plan that growth and equity objectives are not necessarily in conflict, and that the government therefore should seek to pursue a broad-based growth approach.

This study is structured as follows. In Section 2 we provide a short economic history review, while we in Section 3 consider some aspects of the growth-equity trade-off to set the stage. Section 4 provides a review of the recent economic performance and policies. Section 5 shows growth incidence curves for Zambia 1998-2004, while Section 6 reviews agricultural policies, while Section 7 discusses the role of donors in the policy processes. Finally, Section 8 summarizes and concludes the report.

2. Zambia’s Recent Economic History – A Brief Reminder

As a background to the discussion it might be useful to remind ourselves of the recent economic history of Zambia. The country started out at independence as one of the richest of the newly independent developing countries, with a per capita income that was 75% above the African average and about four times that of East Asia (see Diagram 1). Currently, the per capita income is a bit below the African average and about a quarter of that in East Asia.
During the first decade of independence (1964-74), GDP per capita changed little while it increased by 24% in Africa. Still, Zambia saw progress in social outcomes during this period (life expectancy, child mortality, education and under-nourishment) that was similar to that of other developing countries (see Appendix Diagrams). However, from the oil crisis in 1973-1974 and up to the mid-1990s there were severe economic problems and declines in Africa with declining per capita incomes and tightening government budgets. This situation was compounded further by the debt crisis. Life expectancy in Africa started to decline around 1985 (even before AIDS), and there were only small reductions in child mortality and undernourishment.

Diagram 1 about here

Except for education, Zambia’s economic and social development 1974-1994 was considerably worse than the African average (see Appendix Diagrams), and even more so compared to the developing world in general. The Zambian per capita incomes almost halved during the period, and life expectancy started to fall already in 1977 and has declined continuously ever since. Child mortality rose substantially during the 1980s. The magnitude of the decline becomes clear if one looks at the under-nutrition rate, which went from 29% to 48% between 1981 and 1992. However, it has stayed more or less the same since then. Something went terribly wrong in Zambia. Since the mid-1990s there has been some recovery, and Zambia presently seems to grow at about the same pace as Africa (and shows slightly improved social indicators).

Investment is the most classical growth determinant. Diagram 2 shows that investments were high until 1975 with an average of 28% of GDP, which was higher than in East Asia at that time. But then they fell rapidly, and 1979-97 the average investment rate was as low as 14.8%. The investment rate has gradually grown stronger since the mid-1990s and is now around 25%. FDI has started to increase from a low level and is projected to
reach US$480m in 2007, which can be compared to the average US$120m per year in the early part of this decade.

**Diagram 2 about here**

Zambia has in the literature been used as an example of how high aid is not in itself a guarantee for rapid growth. For example, Easterly (2002) computed what per capita incomes in Zambia would have been had all aid gone into investment with normal returns, and arrived at a value of $20,000. In reality, however, the country saw drastically falling per capita incomes, which shows that the available resources were not effectively allocated or used. During the last decade there have been some improvements though, which are to some extent due to the terms of trade gains, but there have also been some improvements in the policy environment.

Mwanawina and Mulungushi (2002) wrote the Zambian contribution to the AERC growth project. They applied a growth accounting approach to analyze the period 1960-2000, and found that capital per worker started to decrease in 1975 and that TFP (Total Factor Productivity) growth was slow throughout. Moreover, when decomposing the growth shortfall in Zambia relative to the rest of the world for the period 1960-2000, they found that capital per worker accounted for 1.96 percentage points, education only 0.01 percentage points, and TFP 0.86 percentage points.

But what explains the low levels of investment and the poor TFP development? While the 1974 oil crisis and general slowdown in the world economy are correlated with the negative development in Zambia, other countries were hit as hard as Zambia, so there must be more fundamental explanations. A major political change had occurred in 1968 when Zambia started a transformation from a free market economy with multiparty democracy into economic nationalization. The reforms culminated in the one party state (2nd republic) in 1972. “The parastatal sector soon was confronted with political inference, inefficiency,
capacity under utilization, lack of accountability and dependency on government subsidies” (Mwanawina, Mulungushi, 2002, p. 2). It was also costly for Zambia to engage in helping neighboring countries in their struggle for independences. Falling copper prices and capital flight contributed to a serious foreign exchange constraint, which led to capacity under-utilization. The first stabilization and structural adjustment program began in 1985, but was followed by a period of policy reversals. Zambia started to reinstate the market economy and multiparty democracy in 1991 although initially with mixed success. Poor sequencing of the reforms, poor institutions and poor governance meant that the environment remained hostile to investment.

Mwanawina and Mulungushi (2002) also undertook an econometric analysis trying to estimate the relative contributions of different factors to Zambia’s growth failure in 1960-97. Direct policies captured by the black market premium and the size of government spending explain 1.8 % of the growth shortfall. The deeper variables of age dependency ratio and life expectancy explain another 2.4 %. Finally, being landlocked explains 0.9 %. It is notable that the terms of trade effect does not have any significant effect. Finally, there was a positive residual of 0.6 %. These are underlying variables that influence investments in physical capital as well as TFP.

Overall, Zambia’s economic development during most of Kaunda’s era (1964-1991) in power was very poor, so there is certainly no basis for any yearning for a return to Kaunda-like policies. The policy changes in recent years have not been perfect, but they have at least been in the right direction.

3. The Growth-Equity Trade-off

Bigsten and Shimeles (2007) analyzed the growth-redistribution trade-off for various African countries, and found that Zambia would need to achieve an annual increase in per capita incomes of 4.0 % between 2001 and 2015 to reduce poverty by half, assuming an unchanged
income distribution (Gini-coefficient). Bigsten and Shimeles also calculated how much the Gini-coefficient in Zambia would have to change to halve poverty if there was no increase in per capita incomes, and found that it would require an annual reduction of the Gini by 2.5% or a total reduction to 0.17 by 2015. This is of course impossible to achieve, but the calculation at least shows the shape of the trade-off. In the case of Zambia with current growth largely based on a natural resource boom, there is instead a high risk of increasing inequality unless policies are in place to manage the distributional consequences of the boom. The challenge for poverty reduction is to achieve a good distributional outcome without jeopardizing long-term growth.

The *World Development Report 2006: Equity and Development* (World Bank, 2006) deals with the role of income distribution policy in poverty reduction strategies, and implicitly takes the view that there is not mainly a trade off between equity and growth, but that inequality instead in various ways is an obstacle to growth that needs to be removed. The focus of the report is not generally on the inequality of outcomes but rather on the inequality of opportunities, and the key recommendation is that a level playing field should be created so that opportunities are equalized. Zambia has for example done this by investing in education. Although this is desirable for reasons of fairness and efficiency there may still be tradeoffs, and we need to understand how actual policies affect both growth and equity.

There is a risk of policy errors if the policy process focuses too much on policies that have short-term poverty-reducing effects. The optimal development path from a poverty reduction perspective would probably best be defined as one that minimizes the discounted sum of future poverty. A policy package that achieves this would be different from one that minimizes poverty in the short term. There are many policies that increase consumption today at the expense of consumption tomorrow. At the same time there are policies aimed to finance investments in infrastructure (e.g., taxation) that generate growth and poverty
reduction in the longer term, while they may have negligible or even negative effects on the consumption of the poor today. Redistribution from the future to the present and from the currently non-poor to the poor can reduce poverty in the short term, but the question that needs to be addressed is how it affects future poverty.

4. Economic Performance, Structural Change, and the Budget

After 25 years of mostly declining real income, Zambia has achieved positive per capita income growth rates in all years since the turn of the century, and starting in 2003 they have consistently been above 2.5% (see Table 1). This means that the Zambian economy has seen a gradual recovery. However, the per capita income level in 2007 will still only be back to where it was in the late 1980s. The recovery started a couple of years before the copper boom in 2004, which has accelerated growth further. The growth objective in the FNDP is to achieve a growth rate of at least 7% and to ensure that it is broad based and rapid in the sectors where the poor are mostly engaged (p 26). We also note that according to the estimates presented in the previous section, Zambia would have needed to grow by about 6.5% per year between 2001 and 2015 to be able to reach MDG1 (reduction of poverty by half). Since the growth rate has so far been below 6.5% since 2001, the rate of GDP growth from now until 2015 required to achieve MDG1 is about 7.7% per year (assuming an unchanged Gini-coefficient).

Table 1 about here

The growth improvement involves most sectors with Mining and quarrying, Manufacturing, Construction, Wholesale and retail trade, and Real estate and business services as driving sectors. Agricultural output has at least expended reasonably well since the 1990s. Historically the share of mining and quarrying has fallen dramatically, but during the last few years it has grown fast. Copper was historically the totally dominating export. Copper production exceeded 400 000 tons annually in the late 1950s, reached a peak
of 700 000 tonnes between 1969 and 1976 before beginning a progressive decline, and in 2000 it was as low as 257 000 (Republic of Zambia, 2007, and DFID, 2006). The copper price fell in real terms until the early 2000s when it was one-third of the 1960-80 price, but has increased dramatically in the last few years and is now about the same as at the 1967 peak level (see Diagram 3).

Diagram 3 about here

The exported quantity of copper has doubled during the last five years, which in combination with dramatic price hikes means that export revenues from copper have increased rapidly. However, also non-traditional exports have increased substantially in recent years, with copper wire and electrical cables having the biggest volumes but also sugar and tobacco doing well. While the current account balance including grants is negative, the overall balance has been positive during the last few years due to substantial inflows of private net capital.

Total exports in dollars have increased fourfold since 2000, reaching 3.3$bn in 2006. This equals approximately 250 (constant 2000) USD per capita, which is back at the per capita level of the early 1980s but still just half of the average 1960-80 levels.

During the period 1995-2003 the Kwacha depreciated not only against the US$ but also against a basket of currencies, although the real exchange rate was quite stable. However, from January 2004 to January 2007 the Kwacha/US$ appreciated from 4767 to 4221 (it peaked in May 2006 at 3185). The exchange rate peaked because of a combination of rocketing copper prices, restrictive money supply by the Bank of Zambia to get inflation down, radical debt reduction, and portfolio inflows.\(^{13}\)

Generally, when faced with an appreciating exchange rate the government needs to think of ways to pursue policies that benefit the survival of the tradables sector. An example of this could be to use the new revenue to reduce exporter costs, such as investment in
transport and energy. The impact of the resource rents on the real exchange rate can also be contained by increasing imports, where the major tool of course is trade liberalization. Policy changes like these of course have distributional consequences that need to be considered.

Although real GDP increased by 34% between 2000 and 2006, government revenue collection (excluding grants) went up by only 16%. This means that revenues as a percentage of GDP slipped from 19.4% in 2000 to 16.8% in 2006. This is to some extent explained by the Kwacha appreciation resulting in a lower Kwacha value of the VAT on imports and customs duty (0.7% of GDP). But the difficulty of bringing especially the agricultural sector and the informal sector into the tax net is a problem. Also, the whole fiscal regime for minerals is too generous to the existing mining houses. The planned increase in royalties will give the Treasury some extra funds, but what is required is a combination of measures such as increased royalties, increased corporate income tax and withholding tax on dividends. The new fiscal regime still does not include a form of windfall tax, which would allow Zambia to get a fair share of the current windfall revenues. We have also seen a piecemeal approach to tax policy in the past, and it is important to expedite the comprehensive review of the tax system (IMF, 2006b).

At the same time, government expenditures as a percentage of GDP have been falling. It is about the same in real terms now as in the beginning of the decade. The overall budget deficit has been kept around 2% since 2004. Budget discipline is of course a positive factor, but expenditures have mainly been kept low due to failures to carry out the budget plans. A key concern with regard to Zambian governance is budget implementation and in particular its consequences for the poverty reduction strategy. There has been some progress with regard to domestic resource mobilization (Zambia Revenue Authority), and at the same time Zambia receives increasing amounts of budget support. However, much work remains to be
done to extend the tax coverage and even more so with regard to the implementation of the existing tax legislation.

It is important to achieve a budget allocation that is relevant for poverty reduction and that strikes a sensible balance between short-term and long-term effects on poverty. In the recent development plan there is an increased emphasis on growth issues that are good for poverty reduction in the longer term, but it is also important that the programs which can have a more immediate impact are functioning well. There seems to be high levels of inefficiency in the ways the government works, and considerable budget resources have not been spent in recent years. In 2006, K8665bn was spent out of the K9942bn in the approved budget. K757bn of the difference is explained by shortfalls in total revenues and grants relative to the targets. However, another K521bn was unspent and only 59% of the approved budget for capital expenditures were used. In 2004 and 2005 the amount not spent was even higher (Republic of Zambia, 2006b).

In this context one might note that the country has an absurdly misaligned budget cycle. The budget decision is taken in Parliament in March, while the budget year starts in January. This means that many activities are put on hold – something that surely makes it harder to meet expenditure and activity targets. However, addressing this problem requires a constitutional amendment which seems to be buried in the slow process to revise the full constitution.

Since we are here concerned with poverty reduction, we need to consider the implication of the fact that the economic expansion is driven by the copper sector. This means that there is relatively limited expansion of formal sector employment, which in turn means that the informal sector has to continue to absorb the bulk of the labor that keeps leaving agriculture. This implies that most of the new migrants will probably earn very low incomes. The CSO (2005) reports that there were approximately 6.7 million persons aged 12
and above in 2004. Fifty-nine percent of these were employed and 6% were unemployed; hence 65% of this age group constitutes the labor force. Almost all of those outside the labor force are reported as full-time students or full-time homemakers. Eighty-one percent of the employed persons were engaged in the informal sector\textsuperscript{14}, up from 79% in 1998. In rural areas this proportion was unchanged at 91%, but the proportion in the urban areas increased from 48% to 57%. The increase in informal employment could partly be explained by the fact that 5% of the population aged 12 and above reported themselves as unpaid family workers in 2004, while less than 1% did so in 1998. Consequently, a new group has been added to the employed. However, the fact that the total number of persons employed in the formal sector has gone up from 740,000 to only 780,000 over the same period shows that the formal sector is not keeping up with population growth.

Another serious problem with regard to poverty reduction is that the government does not collect much tax revenue (directly) from the copper sector (obviously the government is not able to collect significant revenues from the informal sector either), because the firms that bought the copper companies at the bottom of the crisis at the turn of the century were given extremely favorable terms with extensive tax exemptions. The government is now trying to renegotiate the copper contracts, and hopefully something beneficial will come out of this.

Although the government certainly could do more with a larger budget, it is still very important to improve the efficiency in terms of how the existing money is handled and spent. The process of reforming public financial management has been ongoing for a long time, but progress seems to be exceedingly slow. Zambia is introducing an integrated financial management information system (IFMIS) within the PEMFA program to strengthen the system. To get a modern financial management system in place to track expenditures is a central dimension in the reform process. There is not yet a single treasury account, and the cash management still seems to be inefficient.
The government has difficulties both implementing performance assessment indicators and terminating inefficient programs. Decentralization efforts are ongoing, although this seems to be a challenging task. The Auditor General supplies reports with critical information to the Public Accounts Committee, but the actions are decided by the executive. Still, this is done in camera and people are becoming more aware. Large-scale corruption involving for example former President Chiluba is being tackled, but small scale corruption does not seem to be declining according to some observers. The Corruption Perception Index (Transparency International, 2008) has not changed at all since the turn of the century.

5. Poverty and Inequality Outcomes

Zambia is unusually urbanized for being an African country, with an urban population share of 39%. Yet, the country does not have an unusually large share of the labor force in formal sector employment (19% of the employed or 17% of the labor force), since the bulk (66%) of the urban labor force is in the informal sector or unemployed (CSO, 2005). This needs to be taken into account when formulating poverty reduction policy. Still, there has certainly not been any overemphasis on the poor rural inhabitants in the case of Zambia, and reaching those groups will remain the key challenge.

Zambia has conducted at least six countrywide surveys since 1991 to measure the living standards of its people (CSO, 2005). The 2002/03 Living Condition Monitoring Survey III (LCMS III) was an Integrated Household Budget survey; a diary method was used and a 12-month period was covered. The other five were Indicator Monitoring Surveys, one-spot (single interview) surveys. It is therefore not completely appropriate to compare the results from LCMS III with the results from the other surveys. The poverty lines in the Indicator Monitoring Surveys (see Appendix) were originally derived from a 1981 ILO/JASPA basic needs mission to Zambia. The Zambian poverty lines have been based on the Food-Energy...
Intake approach, and in 1991 the cost of the food basket (the poverty line) was updated. The poverty lines were then again updated in subsequent surveys by the change in the CPI (Situmbeko, n.d.) In all of them the calorie requirements per adult equivalent was set at 2721; not at 2450 as recommended by the WHO (CSO, 2004). This of course means that the estimated level of poverty is higher than if the WHO recommendation had been used.

The surveys collected data on household consumption expenditures. Two poverty lines are used by the CSO: The extreme poverty line is the food poverty line, which was K78 223 (1.02 PPP adjusted international 2000$/day) in 2004. The moderate poverty line also includes consumption of “some minimum basic non-food items such as health, shelter and education”. This part is assumed to make up 30% of the consumption bundle of the poor. Thus, the moderate poverty line can simply be constructed as 1/(1-0.3) times the food poverty line, or K111 747 (1.45 PPP adjusted international 2000$/day). This can be compared with the World Bank poverty line of 1.22 PPP adjusted international 2000 $/day (World Bank, 2007b). The World Bank has 28% non-food in the basket defining the poverty line.

The levels of poverty recorded for Zambia by the CSO are significantly higher than those of other African countries at a similar income level. The World Bank (2007a) argues in their analysis of poverty in 2002/03 that the poverty line used by the CSO is too high. While CSO’s moderate poverty line for 2002/03 was estimated to be K92 185, the World Bank estimated it to be K73 394. Their respective estimates of the incidence of poverty were 67% and 56%.

The methodologies used by the World Bank and the CSO to estimate the level of poverty for 2002/03 are similar, but the assumptions underlying the estimations differ in several respects. The first difference between the two poverty line estimates is that CSO sets the calorie requirement per adult equivalent to 2721, while the World Bank uses the WHO (1985) recommendation of 2464 calories. Secondly, there is a difference in how the
consumption basket of the poor is constructed. CSO uses Lusaka prices from the first of the ten cycles in the survey as reference prices, while the World Bank uses national median prices. To determine the food basket underlying the poverty line, CSO calculates quantities by dividing national average expenditure shares by Lusaka cycle one prices. This means that the CSO basket has less of foods that are expensive in Lusaka relative to the national representative food basket. Then both institutions compute district poverty lines using district prices relative to the baseline prices. There are furthermore some small differences between the two estimates in how the price index is constructed. The discussion of the CSO and the World Bank is of some importance with regard to the poverty discussion within Zambia, but it is mainly with regard to international comparisons that it is important to keep measurements consistent across countries. The CSO-estimated poverty line seems quite high, so the World Bank estimate gives a more internationally comparable estimate of the level of poverty in Zambia. However, with regard to changes over time, the level of the poverty line matters less. Here it is important that the procedures to compute the poverty line do not change over time. We will stick to the CSO line in our estimates below for 1998-2004, although we do find that the World Bank line is preferable for some uses.

The 1998 food poverty line was K32 861 per adult equivalent. The CPI adjusted poverty lines from 1993, 1996 and 1998 are updated versions of the 1991 line using CPI (CSO, 2005:112). However, it seems that the 2004 poverty line was not updated accordingly; instead it was updated (with CPI) based on the 2002/03 line, which was calculated from scratch. The increase of the poverty line between 1998 and 2004 is smaller than the CPI increase, suggesting that the 2002/03 computations probably were done based on food prices (which makes sense given the way the poverty line is constructed).

The CSO-estimated poverty levels are shown in Table 2. According to these, national poverty was virtually the same in 2004 as in 1991: The rural level of poverty declined from
88% to 78%, while the urban poverty level increased from 49% to 53%. However, both urban and rural poverty declined from 1998 to 2004.\textsuperscript{16}

**Table 2 about here**

The poverty levels in 1998 and 2004 are estimated using the standard FGT index, which is given as

\[
P_\alpha = \frac{1}{n} \sum_{i=1}^{q} \left[ \frac{(z - y_i)}{z} \right]^\alpha ,
\]

where \(n\) is the total number of households, \(q\) is the number of households below the poverty line, \(z\) is the poverty line and \(y_i\) is the consumption of household \(i\). For \(\alpha = 0\), the FGT index reduces to the head-count ratio \(H\); for \(\alpha = 1\), it is the poverty-gap or depth of poverty; and for \(\alpha = 2\) the FGT index has been interpreted as indicating the severity of poverty.

**Table 3 about here**

We see (Table 3) that poverty is much more widespread and severe in rural areas. The positive news is that the rural depth of poverty fell from 0.72 in 1991 to 0.50 in 1998, and then finally to 0.44 in 2004.

Next we take a closer look at how the poverty changes have been brought about, using the approach of Datt and Ravallion (1992). They devised a simple decomposition algorithm able to decompose the change in poverty between two points in time into one part due to per capita income change and one part due to inequality change plus a residual. If we apply this approach on the change in poverty from 1998 to 2004, the basic formula is

\[
P_{04} - P_{98} = G(98, 04) + D(98, 04) + R(98, 04) .
\]

The growth component \(G\) and the redistribution component \(D\) are given by

\[
G(98, 04) = P(z_{04} / \mu_{04}, L_{98}) - P(z_{98} / \mu_{98}, L_{98})
\]

\[
D(98, 04) = P(z_{98} / \mu_{98}, L_{04}) - P(z_{98} / \mu_{98}, L_{98}) .
\]
where e.g. \( P(z_{04}, \mu_{04}, L_{04}) \) is the poverty level that Zambia would have had in 2004 with a 1998 income distribution and a 2004 per capita income level. Since the poverty measures used are not additively separable, we get a residual component \( R \).

We have used this method to decompose the change in moderate poverty from 1998 to 2004. This decomposition is based on the official poverty lines, even though we have some concerns about them as discussed above. Our consumption expenditure per adult equivalent based Gini coefficients are 0.533 for 1998 and 0.544 for 2004, indicating that there was a slight increase in the Gini coefficient over this period.\(^{17}\) Tables 4-6 report our results.

Tables 4, 5 and 6 about here

The results for changes in moderate poverty show that growth contributed significantly to poverty reduction in 1998-2004, both in urban and rural areas. Although there was a modest poverty increasing effect from the inequality increase, overall poverty still declined substantially. Since Zambia is a very unequal society with a Gini coefficient almost as high as that of South Africa, there is an underutilized poverty reduction potential from policies aimed at decreasing inequality. We see that the negative effect of income distribution change on poverty is somewhat more pronounced in urban areas than in rural areas. We repeated the same calculations for extreme poverty for the period 1998-2004, and found the same pattern there.

Poverty is clearly more severe in rural areas, but we also note that income growth has been somewhat better there than in urban areas. The incidence as measured by the head count is of course much higher, but the urban-rural differences are even larger when comparing the depth and the severity of poverty. The results are in line with indicators such as life expectancy, undernutrition and child mortality, were Zambia has been scoring worse than Africa in general since around 1990 (see Appendix Diagrams). Hence, even if poverty is being urbanized in Africa, it is still overwhelmingly rural.
To characterize the growth pattern further we have constructed growth incidence curves for total, rural and urban Zambia. These curves show how consumption growth varies across deciles of the population, and how average real household consumption increased from 1998 to 2004. The curves are deflated by the poverty line.

For total Zambia we can see that all deciles experienced positive growth during the period (Diagram 4). There is no clear pattern of differences across income levels. The results for rural Zambia shown in Diagram 5 indicate that the bottom decile has done really well, but one needs to be cautious not to read into this too much, since measuring there is problematic. These are households with very low incomes. Apart from the bottom decile, the curve slopes generally upward, indicating that the better-off farmers on the whole did somewhat better than their poorer colleagues. When it comes to the urban growth incidence curve (Diagram 6), we see that the bottom of the distribution has done slightly better than the intermediate range, while the richest urban decile in particular was successful. It is perhaps not surprising that the better off in particular benefit when there is acceleration in the growth of the economy.

Diagrams 4,5 and 6 about here

6. Agricultural policies

In the 1980s, up to 17% of the national budget was devoted to maize and fertilizer policies, but these were then scaled back. However, in recent years as much as 70% of the Ministry of Agriculture budget has gone to fertilizer subsidies and maize marketing and stockholding programs. Only 20% of small farmers use fertilizers in Zambia. The farmers’ effective demand for fertilizers must be built up by making it profitable to use, which includes developing output markets and regional trade patterns. Jayne et al. (2007) argue that “sustained investment in crop science, effective extension programs, physical infrastructure and a stable and supportive policy environment” is where public sector resources can make
the best use. Targeted assistance to vulnerable households is important but should not interfere with the long-term development of agricultural markets.

Since the bulk of the poor in Zambia still are found in rural areas, it is of course vitally important to develop agriculture and other rural economic activities. Development of agriculture is also important to bring about the structural change required for long-term growth. Still, the introduction of a complex set of subsidy programs via local governments and cooperatives does not seem to be the most efficient route to improve rural incomes. This has meant that the private network sellers of fertilizers are in trouble, and many do not even hold fertilizer stocks any more since their market has been taken away. Local traders and network sellers need a predictable environment to get incentives for a long-term engagement in the sector. The recent huge government maize purchase is a signal pointing in the wrong direction. The private traders who had entered the business are squeezed.

The Food Reserve Agency should be just that and not a last resort buyer. The policy in this area was rather straightforward until the last election when the purchase of the Food Reserve Agency shot up from 50 to 400 thousand tonnes. The surplus was supposed to be exported but that has still not happened. Instead there seems to be a high risk that much of it will be wasted. The government seems to have had a roadmap for private sector growth in agriculture, but now there seems to be a move of policy thinking towards more state interventions and subsidy schemes. Now subsidized fertilizers are sold through farmers unions and the like, and the well-connected people end up getting access. There are suggestions that there are very extensive rent-seeking activities going on, where the elite get the cheap fertilizer and then sell it on.

Hence, the introduction of these subsidy schemes is problematic not only from an efficiency perspective but also from a distributional point of view. Since 75% of farmers do not sell maize at all and a small 2% minority sells half of it, the distributional impact of these
subsidies is skewed. The subsidy scheme has also had other distortionary effects. Since the
guaranteed prices are higher than in neighboring countries, it seems obvious that maize is
carried over the border and sold into the Zambian reserves. There are at least four places
along the borders where the buying stations have bought much more than the local farmers
sold (so-called ghost sales).

There is high variation within districts in terms of land ownership, and land ownership
is a key income determining factor. The issue of land ownership has not yet been sorted out.
In areas under traditional tenure (94% of the land), the chief decides on allocation of land.
Everyone is supposed to have land according to capability, but this is of course a flexible
concept. Influence seems to matter a lot as well. Local allocation of land in fairer ways seems
highly important. Insecurity of tenure may have significant effects on the willingness of
farmers to invest and on their ability to use land as collateral for loans to finance investments.

Bigsten and Tengstam (2009) show that smallholders in Zambia are dependent on a
whole range of off-farm incomes, and that it therefore is important not to look at rural
policies as only those that concern agriculture. Paving the way for diversification is also a
key in a package of poverty-reduction policies. Infrastructure that facilitates activities other
than agriculture of course includes many things that are also beneficial for agriculture, e.g. a
good transport infrastructure. The diversification route to higher incomes for rural households
requires a well-functioning economic environment and general policies that make it possible
for new activities to emerge.

7. Donors and Governance

We have argued in this report that the formulation of policies and probably even more the
implementation of those policies is a key challenge for Zambian development. We conclude
with a brief discussion of what this implies for donors.
The donors have developed a Joint Assistance Strategy for Zambia (JASZ), which is related to the Fifth National Development Plan. This is to provide an analysis and a basis for the collaboration. JAS has a lead donor concept, which is almost fully implemented. Also, the coordination of donors is a complicated process. The Zambian aid policy is now approved. The aid department (ETC) is working more or less as it did 20 years ago, but is currently revising their structure to allow for the donor coordination efforts. The Fifth National Development Plan is generally sensible in terms of overall policy direction, but the challenge is to implement the policies especially since governance in Zambia remains weak. This is or should be the key concern from a donor point of view with regard to development cooperation with Zambia.

Collier (2006) discusses aid collaboration in Africa and notes that the resource-rich countries often have had large and corrupt government sectors, since they have been able to earn sizeable resource rents which accrue to the government. Although the resource rents accruing to the Zambian government today are very much reduced compared to the initial decades after independence, the current system nevertheless emerged under those circumstances. Collier argues that the appropriate strategy towards countries in this category is to find ways to improve the efficiency by which they spend public money, through knowledge transfers and governance conditionality trying to make the government more accountable to its citizens. For rents (and aid money which also can be seen as a sort of rent) to be effectively used it is probably necessary that power is more widely diffused. The development of good systems of public spending can be supported by appropriate technical assistance. There is a strong need for proper project evaluation techniques to be incorporated in the PEM systems in Zambia. Transparency and accountability mechanisms are certainly important, but one must not forget that bad policies will have poor impacts and results even if they are implemented transparently and with full accountability.
Policy conditionality was not very successful in dealing with the problems of elite capture. The alternative of governance conditionality aimed at weakening the dominance of the governing elite was proposed by Collier (2006) as a better alternative. Unfortunately there is a knowledge gap about how to implement governance conditionality. A parallel constraint is the lack of administrative capacity in the civil service, which needs to be developed by various forms of technical assistance. Technical assistance needs to be aligned with the new paradigm of ownership and control.

Democracy has two dimensions: electoral competition and checks and balances. Particularly resource rich countries need democracy to avoid elite capture of rents. They also need checks and balances to prevent elections from being converted into corrupt patronage games financed by the resource rents. One needs system scrutiny to achieve honesty and other systems to achieve efficiency. Since scrutiny is a public good it is subject to collective action problems, and donors could possibly take a role to stimulate peer group evaluations. The donors could help improve the information to the principals (citizens) and build up their capacity to analyze it, and help promote incentives for government agents to act in accordance with the wishes of the principals. Audit systems and parliamentary scrutiny are key areas of intervention, and these are both part of the PEMFA program.

A key aim of donors in Zambia should be to improve governance and implementation capacity. This may require governance conditionality combined with technical assistance to build up systems that can handle government resources in a transparent and accountable way. Zambia has reformed economic policies extensively and the current FNDP seems reasonable. How well the government will succeed in achieving growth and poverty reduction will depend on the amount of resources it can mobilize, but it is also crucially important that the government is able to implement policies effectively.
8. Concluding Remarks

This paper started with a discussion of Zambia’s economic development up to the present phase which is characterized by a resource boom. We discussed current economic policies, and provided our own empirical estimates of changes in poverty, mainly from 1998 to 2004. Against this background we considered the appropriateness of economic policies for poverty reduction. The focus has not been on the macroeconomic issues which have been dealt with extensively by others, but instead on micro and structural issues.

We found that poverty as measured by the head count index declined by about 5.4 percentage points. We decomposed this change into a 6.6 percentage point reduction due to growth and a 1.2 percentage point increase due to a slight change in inequality. We also looked at the growth incidence across consumption deciles. According to our estimates all deciles experienced an increase in consumption between the two years. Overall the increase seems to have been somewhat larger in rural areas, with the exception of the top urban decile which experienced a rapid consumption increase. Still, poverty remains much more severe in the rural areas than in the urban areas. We also note that poverty leads to undernutrition, that life expectancy in Zambia is among the lowest in the world, and that under-5 child mortality is very high.

We saw in our analysis of the pattern of smallholder income growth that diversification is a very important route out of poverty for the rural poor in Zambia. Policy makers should thus keep in mind that rural household incomes are not from agriculture alone. A major focus should be on measures that strive to facilitate the diversification process. Typically, these are policies that develop the overall economic environment and help smallholders get better market access. Agriculture is a major part of the private sector in Zambia, and should receive higher priority in policy.
The government often has sensible private sector development policies, but according to several observers they are implemented poorly, slowly and reluctantly. This is the classical Zambian problem of a disjoint between sensible policy analyses and the capacity and willingness to implement the policies. Policy is often inconsistent as to what to do with the private sector. It seems as if the government likes interventions to be specific rather than general. The reluctance to move away from ad hoc government interventions may in part be due to the lingering Kaunda romanticism.

So what are our policy conclusions? First, we saw from the review that tax revenue collection has not kept pace with GDP growth, one reason being that the copper boom generates little direct tax revenue. Another reason is that most employment is within the informal sector, where hardly any tax is collected. Still, the poor tax buoyancy is a concern from a poverty reduction perspective, because collecting tax revenues and using them for poverty reducing expenditures would have been one of the main ways to channel resources from the boom to the poor.

Second, we noted that the government is very inefficient in realizing its expenditure plans. This is a reflection of the generally low level of efficiency in the public sector, and it is absolutely essential that the financial management reforms are speeded up. Smooth and transparent reporting is key for domestic accountability and also for development cooperation. An important reform to undertake would be to change the budget cycle. It certainly seems absurd to decide on the budget in the Parliament in March when the budget year starts in January!

Third, we noted that improved public sector efficiency is crucial if reforms are to function properly. We discussed various issues relating to transparency and accountability, and the importance of monitoring by the electorate, the donors and by government institutions such as the Auditor General.
Fourth, it is clear that the focus of poverty oriented policies will largely have to be on the rural sector and agriculture, since rural poverty is much more extensive than urban poverty. Since Zambia is a very unequal society with a high Gini coefficient, poverty levels could also be reduced via a lowering of inequality. But since the average income and consumption is extremely low, growth is crucial for poverty reduction. To make agriculture more efficient and to reduce rural poverty, resources should be used in line with the FNDP to improve infrastructure such as roads and electricity, extension services and education rather than for subsidy schemes. More than half of the Ministry of Agriculture budget has gone to fertilizer subsidies (mostly for maize) and maize programs. However, there has been diversification and in recent years it is for example cassava, sweet potatoes and livestock production that have performed well. Secure property rights are of course also a crucial determinant of rural investment. While the FNDP emphasizes the measures just mentioned, implementation in these areas seems to be slow.

Fifth, there are some good intentions in the private sector development strategy, but implementation again seems to be inefficient. The government still seems to focus too much on the need to control and intervene in details, while it would be more efficient to do away with excessive interventions. If Zambia is to be able to reach an economic take-off, the country must be an attractive destination for both foreign and domestic private investors. Apart from a better business environment the infrastructure must be improved (particularly since Zambia is landlocked), and the country needs a successful completion of a new trading arrangement with the EU.

Sixth, even if there is a need for policies towards the productive sectors, the very important areas of poverty relevant social services such as health and education remain vital. The health sector needs to be strengthened both because it has an immediate effect on welfare and because it helps build and protect human capital that is essential for long-term growth.
Seventh, social protection might have a role to play, but it is probably not possible to expand this fast. It might be possible to use schools for channeling resources to the poor. By having e.g. free school lunches and school uniforms, a certain amount of “child support” would be provided and school attendance would be encouraged at the same time. There are also some interesting but small-scale experiments of social protection done with donor support. For example, the Ministry of Community Development is currently experimenting with a cash transfer scheme in the South that seems to hold some promise. There is of course a concern as to the ability of the system to upscale this, and the cost implications of that have not yet been analyzed.

Eighth, we have repeatedly noted that improved governance is the key to successful development, An idea that has been floated is that donors should shift to some form of governance conditionality. This would mean a concentration on achieving a transparent and accountable process rather than on achieving specific decisions.

We would like to thank officials of the Zambian government and other institutions for very helpful discussions. We are grateful to Jos Verbeek for useful comments and to Abebe Shimeles for help with the poverty analysis. We would also like to thank Michael Weber and Antony Chapoto for sharing their data on Zambian agriculture with us. Finally, we are grateful for all the help received from Eva Lövgren and other staff at the Swedish Embassy.

Commodity prices are generally volatile and unpredictable. The typical pattern has been a rapid price increase when there is a stockout of the commodity (when stocks fall below some level that is considered acceptable) (Collier, 2007). This abrupt increase in the price of a commodity is then generally followed by a slow long-term decline. The pattern one observes is consequently one with short periods of very high prices with slowly falling prices in between. Zambia currently has extremely high copper prices, but experience from other such periods thus seems to suggest that it will be followed by a long period of declining prices.

Countries have generally found it difficult to handle commodity booms (Collier and Gunning, 1999, O’Connell and Ndulu, 2006), and Zambia has previously had problems handling resource incomes in an effective manner (Bigsten, 2001).

In the early 1980s the international community throttled the inflow of loan money to less than debt service levels (net flows became negative). This contributed to cutbacks in government expenditures and lower investments both in the social sectors and in infrastructure.

Geography is important (Sachs and Warner, 1997, and Bloom and Sachs, 1998) as it could either undermine the health of workers or impose high transactions costs. IMF (2006b) estimates the annual population growth to 2.4%, but World Bank (2007b) reports an average rate of 1.9% for the period. The total gross value of agricultural output rose by over 50% between the mid-90s and 2001-2004 (Jayne et al., 2007), and grew annually by 3.8% 2003-2006 (Republic of Zambia, 2006a and 2006b). A debt management system is under way with the help of the IMF and the World Bank. Maybe large new loans will have to pass the Parliament. The country is more creditworthy again, but for the time being the government is not in any shape to start taking large new loans. Informal sector employment is defined as employment where the employed persons are not entitled to paid leave, pension, gratuity and social security, and work in an establishment employing five persons or less. Poverty levels generally change with the seasons. The 1993 survey was conducted April-June, which is a season when the poverty level is approximately three percentage points lower than the yearly average. The other four surveys (except 2002/03) were conducted when poverty levels were in general 3-5 percentage points higher than the yearly average (World Bank, 2007a:54). The Gini coefficient for income is estimated by CSO to be 0.57 (Zambia, 2006c, p. 16). Our estimate of the Gini coefficient for the distribution of per adult equivalent consumption is slightly lower at 0.544. Consumption distributions tend to be more equal than income distributions. Currently partners in Poverty Reduction Budget Support to Zambia monitor progress against agreed benchmarks drawn from the Zambian FNDP... Partners could consider withdrawing aid when the recipient moves away from commitments to poverty reduction, human rights and other international obligations, or sound financial management. The per capita 2006 spending on health was US$ 16.7 (Kwacha 51 500) or 1.5% of GDP, so the consumption of (publicly provided) health is very low. The AIDS situation in Zambia is extremely serious; apart from the human suffering it causes shortages of essential labour. The missing staff must be replaced, which probably leads to higher wages. This is an area where the need for increased intervention is obvious, and here for example the Zambian Government, the Global Fund and PEPFAR provide resources covering ARVs for infected persons. Since the costs of drugs are covered by the donor this does not seriously crowd out other government projects, although there are administrative burdens in association with the administering of the project. The largest social protection scheme in the country is the World Food Programme, which provides food for 10-15M$ every year reaching 300-400 thousand people/children. This might be too low, since it is calculated from the population growth reported by IMF (2007b), which is high. Note that IMF and World Bank (2007b) in general have the same figures for Zambia 2000-2005 for real GDP growth, but IMF on average reports 0.6 percentage points higher population growth rates, and 0.6 percentage points lower GDP per capita growth rates. The extra high poverty levels this year when taking the underestimation into account are probably explained to a large extent by drought.
