Abstract

The aims were to compare clinical effectiveness, functional and social discomfort, explore and describe preadolescents’ experiences of treatment, and assess the costs of reducing large overjet with an Andresen Activator (AA) and a Prefabricated Functional Appliance (PFA).

Subjects and methods: A multicentre, prospective randomized clinical trial was conducted with patients from 12 general dental practices. Ninety-seven patients with an Angle Class II, Division 1 malocclusion, and an overjet of ≥ 6 mm, were randomly allocated by lottery to treatment with either a PFA or an AA. The study was designed as intention to treat (ITT), and the endpoint of treatment was set to overjet ≤ 3 mm, followed by a 6-month retention period.

The PFA and AA group consisted of 57 (28 girls, 29 boys), and 40 subjects (16 girls, 24 boys), respectively, with a mean age of 10.3 years. Overjet, overbite, lip seal, and sagittal molar relationships were recorded before and at the end of treatment, and 1-year post-treatment. One month and 6-months after treatment start, a questionnaire addressing discomfort, perception of treatment need and outcome, was used. Individual interviews focusing on adolescents’ experiences of using a removable functional appliance were carried out with 21 adolescents.

Direct costs and indirect costs were analysed with reference to ITT (intention-to-treat), successful, and unsuccessful outcomes. Societal costs were described as the total of direct and indirect costs, and did not include retreatments.

Results: No difference in effectiveness could be shown between PFAs and AAs in correcting overjet, overbite, sagittal molar relationship, and lip seal. No difference in experienced functional and social discomfort after 6 months of appliance wear was seen between groups. Participants developed their own strategies of measurement for improvement. The results clearly show that in terms of cost-minimization, PFA is the preferred approach for reduction of large overjet in mixed dentition.

Conclusions: PFAs are as effective as AAs in correcting overjet, overbite, sagittal molar relation, and lip seal. The success rate of treatment with both appliances is, however, low. Thus, the PFA, requiring lower costs, should be used for reduction of large overjet in mixed dentition.

Keywords: Orthodontics, preadolescents, large overjet, overjet reduction removable functional appliance, discomfort, phenomenography, interview, cost assessment.
