# 1. Europe and its Media

#### 1.1 Introduction

A traditional idea where countries marked with high level of democracy also has high levels of media freedom, and that country with low level of democracy has oppressed and cowed media is both excessive and very simplistic. But it is nevertheless the image that formed the basis for our understanding of the relationship between media and political systems. The media is attributed to positive or negative characteristics and functions depending on whether the country they operate in has a high or low level of democracy. This picture is confirmed when we study some media, but it is considerably more complex when we study other media.

How we relate to media and the relationship between media and political institutions is based on what role the media should play in society and how the media should respond to the governing and the governed in the society (Asp 2006:245). These normative theories of media then work as reference points in assessing various countries' media, and provide opportunities to systematize the relationship between media and political institutions (see, e g Siebert et al 1956; Mughan and Gunther 2000; Bertrand 2003; Hallin and Mancini 2004).

The relationship between media systems and political systems has great importance for our understanding of the media and the role they play in a society, but there are other aspects of countries' media systems that also are important to compare systematically. If, how and under what circumstances can independent, competitive and pluralistic media increase the quality of government institutions? In order to enable comparative analysis of the media system mechanisms that produces quality of government (QoG). A first step is to compile comparable characteristics of the European media landscape and to examine what indicators of different media systems that is comparable. This paper focuses on the media systems and establishes a set of mechanisms of the independent variable necessary to enable more powerful tests and systematic elaborations of the relationship between media and OoG in the future.

#### 1.2 Research Questions and the Focus of the Study

The aim of this paper, with its point of departure in Hallin and Mancinis already classic book *Comparing Media Systems* (2004), is to study European media systems based on population structure and media consumption, in order to answer the question about whether the patterns of Hallin and Mancinis ideal models can be observed also when studying media systems from a user perspective. On the basis of systemized and

comparable statistics, another aim is to examine the differences between media systems and the factors underlying these differences.

A first step is to identify and systematically compare *how* and in what way media systems in Europe are similar or different from a user perspective. In the next step it is then possible to look for explanations to *why* some media have greater scope and impact in some parts of Europe and not in others. This paper should be seen as a first step in this process; as a contribution to Hallin and Mancini's previous studies and as an attempt to answer the question of how. The answer to this question results in the next step forward, i.e. to the possibilities to look for an answer the question of *why*, (something that is not implemented in the context of this paper). To achieve the purpose of the paper, my intention is to answer the following questions:

- Is Hallin and Mancini's ideal models valid when the European media systems are compared on the basis of structure, access and consumption?
- In what respects confirms or weakens the user perspective Hallin and Mancini's ideal models?

The paper, just like Hallin and Mancini, puts the primary focus on countries' media system, but from other dimensions. Hallin and Mancini are studying how media markets have developed over time (with emphasis on mass-distributed daily newspapers, the relationship between media and the political power, journalistic professionalism and the political influence over the media system). This paper covers roughly the same number of countries that eventually formed part of Hallin and Mancini's study from 2008, but put emphasis on the daily press, television, and the Internet. Furthermore, media systems are studied from a user perspective, meaning that factors like structure, access and consumption are under focus. In this way, this study adds another important dimension to Hallin and Mancini's ideal models.

#### 1.3 Outline

This paper consists of three sections and the disposition is as follows: section one provides a brief overview of the research on how we look at media systems and the relationship between media systems and political systems. Then I go on to discuss the material this paper is based on, and how the methodological approach was done to implement this study. In section two, the paper's findings are presented, and the section concludes with a reconnection to Hallin and Mancini's ideal models. The paper's third section consists of two appendixes; the first appendix is an overview of the countries included in the survey. Appendix two is a detailed presentation of the statistics that the paper's findings are based on. The idea behind this arrangement is that the reader should be able to use the paper's various parts for his or her specific purpose. Some may wish to read the full paper; others just want to use specific parts.

# 2. Earlier Research on the Relationship between Media, Media Systems and Political Systems

#### 2.1 Four Media Ideologies

The view of the media as an influential actor in political life is based on differences in the perception of the media and its functions in different countries. As already mentioned, there have also been several attempts to systematize the relationship between mass media, media systems and political systems. Traditionally, the common way to divide the concept of mass media is in four different media, or information ideologies. These ideologies are originated in the Hutchins Commission attempt to classify the relationship in the 1940s, which came to identify four different categories: (1) The Authoritarian Ideology, where the policy-makers control the press, radio and television, and where there is active suppression of inappropriate expression of opinions and unpleasant news. There is therefore censorship of the media in which only those who are in solidarity with the current system may be heard; (2) The Libertarian Theory, where citizens are presumed to be active and interested in creating public opinion. Mass media is seen as a key means of advancing ideas and anything that can prevent free formation of opinion must be countered. The media must be completely free from political decision-makers and act as a fourth estate alongside the government and parliament; (3) The Social Responsibility Ideology, which emerged as a criticism of the libertarian ideology in that it in fact also has been considered as the same as freedom from responsibility and moral obligations - freedom has become a freedom for the owners of mass media and certain political elites - but not for the majority of consumers. Proponents of the social responsibility ideology therefore believe that ideology should be revised and supplemented with different requirements designed by the media themselves, empowerment of journalists or certain governmental obligations; and finally (4) The Soviet Communist Theory, where the media and especially the press, played a significant role. Newspapers must be in the party establishment and function as an instrument in the construction of the new communist society. Press freedom in this approach is not synonymous with freedom for the owners, but contributes to the liberation through enlightenment (Hadenius, Weibull and Wadbring 2008:23f).

In 1956 Fred S. Siebert, Theodore Peterson and Wilbur Schramm made a classification of the different normative conceptions of what role the media should play in a society. In the book *Four Theories of the Press* (1956) they confirm in principle, the Hutchin Commission classification, and the outcome was four normative theories based on two fundamental conceptions of what role the mass media should play in society: one democratic – The Libertarian and The Social Responsibility Model, and one non-democratic – The Authoritarian and The Soviet Communist Model. Both the Hutchin Commission and the mass media ideologies designed by Siebert, Peterson and Schramm are ideal types that point at some basic media political divides. They appear, therefore, rarely in only one form in a country, but to different degrees in different media. It should also be added that the categorization is more than fifty years old and that the development

of new information and communication technology has opened up new technologies and, thus new media ideologies (see, e.g., Castells 2000).

#### 2.2 Hallin and Mancini's Four Media Models

The efforts to classify the different countries' media systems do not stop at *Four Theories of the Press*. Half a century later, namely 2004, Daniel C. Hallin and Paolo Mancini conducted a comprehensive comparative study that explore the role a country's political and economic system play for the media system quality. Hallin and Mancinis study is based on the Siebert, Peterson and Schramm ideal models, but the authors argue for that you can not understand media and media systems without being familiar with the specific nation characteristics, the party political system, the relationship between economic and political interests and, the development of civil society. Siebert, Peterson and Schramm took the media as something which has always influenced and changed in relation to society which they regard as their point of departure. Instead, Hallin and Mancini argue that the media institutions both reflect the society they operate in and on their own, affect social structures. The mass media has gone from being a tool to be an actor influencing and changing the society they operate in (Hallin and Mancini 2004:8).

Through their study in 2004, Hallin and Mancini identify and distinguishes three fundamental ideal models for the relationship between media systems and political systems: (1) The Mediterranean/Polarized Pluralist Media Model, which is characterized by countries that have democratized relatively late, a strong government intervention in the economy and an elite-oriented press with relatively small editions. The public service companies tend to follow national governments and parliamentary systems, such as if the leadership and political orientation changes after parliamentary elections similar changes is implemented in the public service companies. Journalism is less professional and the links between political actors and journalists are strong, while the legal system is relatively weak. Examples of countries that are placed in The Polarized Pluralist Model are Greece, Portugal and Spain; (2) The Northern European/Democratic Corporatist Media Model is characterized by countries with a long democratic tradition. Politics is characterized by consensus and a strong state with a wellgrounded legal system. The publishing sector is an important part in the Democratic Corporatist Model. There is competition in the market for print media, but despite this the market is regulated through various political and cultural activities such as press subsidies. Other features are non-commercial public service and a high degree of autonomy for the broadcasters. The journalism is professional and self-regulating with common ethical standards for radio, television and newspapers. Examples of countries that are placed in this model are Sweden, Norway, Denmark, Austria and Germany; (3) The North Atlantic/Liberal Media Model is instead characterized by countries with a long tradition of democracy, strong and widespread press freedom and strong individualism. Newspaper circulation is relatively high, although lower than for the countries of the Democratic Corporatist model. Politically, most of the countries have a majority system. Generally, the media are not strongly linked to the government and political parties, but are instead governed by commercial interests and the journalistic professionalism is

relatively strong. Countries that are placed in The Liberal Model is for example United Kingdom, USA, Canada and Ireland.

In 2008 Hallin and Mancini, together with a number of researchers, conducts a study based on the three ideal models identified in 2004, but now complemented by a fourth ideal model: (4) The Eastern European/Post-Communist Media Model, to include the Eastern European countries that were excluded from the study 2004. The reason that these were not included in the analysis in 2004 was that they differed from other European countries regarding the relationship between newspaper distribution and socioeconomic factors, which in turn was a consequence of the rapid changes occurring in the countries since the collapse of the Eastern bloc.

The countries in the fourth ideal model have, strictly speaking, not much else in common concerning history, culture, religion and level of development than just the history of communism and the communist system. Just as the countries in The Polarized Pluralist Media Model, the post-communist countries are characterized by late democratization and incomplete, or for some countries, very complex modernization, combined with strong state control, widespread clientelism, and state paternalism. The newspapers and newspaper media underwent major changes from 1989 onwards. When the state monopoly on the newspaper market disappeared, this meant, for example, that a flood of new newspapers emerged and the number of regional and local newspapers increased markedly. Broadcast media is struggling to keep their independence and to demonstrate political independence, but still work as political actors who actively strive to promote the ruling power.

The starting point for both analysis by Hallin and Mancini is four dimensions that the authors also use for defining the concept of *media systems*, and in which they find it fruitful to compare different countries' media systems. The first dimension is how different countries' media markets have evolved over time, with an emphasis on a strong or weak development of the country's mass distributed daily newspapers. The second dimension of their study is political parallelism, i.e. the link between the country's media system and the political power, and how the media systems reflect the political power and the country's political system. The third dimension examines the development of a journalistic profession and the scope of journalistic professionalism. Finally, Hallin and Mancini study the prevalence and manifestations of political power, the influence and impact of political power on the media system (c.f. Blumler and Gurevitch 1995).

This paper is based on the Hallin and Mancini's four ideal models, but with main focus on the countries' media systems from a user perspective. Although this means that the paper has its origin in the focus that Hallin and Mancini put on the relationship between media, media systems and political and economic systems, the operational indicators are different from these implemented by Hallin and Mancini.

The focus and main point of this paper is therefore that it adds new dimensions to the body of knowledge provided by Hallin and Mancini. Dimensions like media structure, the inhabitant's possibilities to get access to the media, and how the usage and consumption

of media is manifested in practice are three very important factors that play a major role in the understanding of countries' media systems. Hallin and Mancini's study exemplifies that it is possible to classify the different countries' media systems in different ideal models and that the differences and similarities in the dimensions follows, albeit with a few exceptions, consistent patterns.

Are the same patterns observable also when countries are compared on the basis of structure, access and consumption, or will the ideal models split up when we supplement with other dimensions in our comparisons? Whatever the outcome will be, this leads us further towards important knowledge when it comes to describing and understanding the relationship between media, media systems and political systems.

#### 3. Material

The material used in this paper is based on secondary data mainly collected from four separate sources. Data and statistics on the European newspapers are collected from the World Association of Newspapers and their compilations of cross-country statistics in the World Press Trends 2007. The statistics includes dimensions such as the total number of newspapers, where newspapers referred to papers published at least 4 days per week, average circulation, and share of national and regional newspapers, total daily reach, and share of total advertising expenditures. Data on television is collected from IP International Marketing Committee, Key Fact Television from 2007 and includes dimensions such as number of households with television, viewing time, reach, and the share of total advertising expenditures. Data on the Internet and broadband usage is collected from the Eurostat web-based statistical database and includes dimensions such as share of individuals who regularly use the Internet, share of households with access to broadband and share of total advertising expenditures. Finally, this paper also includes data on ethnic, religious and linguistic fictionalizations, literacy, freedom of the press and the political, legal and economic impact on media content, political systems, number of years of consecutive state and degree of democracy from the Quality of Government *Institute*. In addition to these four main sources, data on countries' demography and economics is collected from the World Bank, which includes GDP and GDP per capita, and the country's area.

The selection of countries to be included in the study has first and foremost been based on the availability of reliable data. The ambition is that selection of cases should correspond and include the same countries that were part of Hallin and Mancini's study 2008, but at the same time to take a holistic approach and include all media systems and a complete range of European countries, to create an overview of the media systems throughout Europe as a whole. Europe consists of no less than 51 countries and it turns

\_

<sup>&</sup>lt;sup>1</sup> The study conducted in 2004 included 18 countries: Austria, Belgium, Canada, Denmark, Finland, France, Germany, Greece, Ireland, Italy, Netherlands, Norway, Portugal, Switzerland, Spain, Sweden and USA

The study conducted in 2008 included 32 countries: Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Iceland, Italy, Latvia,

out pretty quickly that the availability of comparable data varies between different countries (see appendix I). It is relatively easy to find reliable media data for the member countries of the EU, the OECD and countries in both the West and Southern Europe. The lack of comparable and reliable data becomes, however rather obvious when the focus is either expanded or moved to countries in Eastern Europe. It is still, in year 2008, incredibly difficult to find reliable media data for countries such as Russia, Georgia and Ukraine.

The lack of comparable data limits the opportunities to draw some general conclusions about the dimensions of the media system, but it also means that the number of countries, after all, varies depending on the dimension that under study (from a minimum of 31 countries to a maximum of 45 countries. Hence, there are some problems when it comes to cover all European countries - some countries are simply not included in the analysis. The intention is to extend the study to also include those countries that are not member of either the EU or the OECD. In light of the collected data you can however conclude that it is precisely these countries that all too often lack reliable and comparable data.

Thus, this paper mainly focuses on the analysis of national dimensions of media systems and includes 45 of Europe's 51 countries. The countries included are the following:

Table 1 Countries included in the study

Albania	ALB	Georgia GEO		Nether-	NLD
Andorra	AND	Germany	DEU	lands	NLD
Armenia	ARM	Greece	GRC	Norway	NOR
Austria	AUT	Hungary	HUN	Poland	POL
Azerbaijan	AZE	Iceland	ISL	Portugal	PRT
Belarus	BLR	Ireland	IRL	Romania	ROU
Belgium	BEL	Italy	ITA	Russia	RUS
Bosnia and	він	Kazakhstan	KAZ	San Marino	SMR
Herzegovina	ып	Latvia	LVA	Serbia	SRB
Bulgaria	BGR	Liechtenstein	LIE	Slovakia	SVK
Croatia	KRO	Lithuania	LTU	Slovenia	SVN
Cyprus	CYP	Luxembourg	LUX	Spain	ESP
Czech Republic	CZE	Macedonia	MKD	Sweden	SWE
Denmark	DNK	Malta	MLT	Switzerland	CHE
Estonia	EST	Moldova	MDA	Turkey	TUR
Finland	FIN	Monaco	MCO	Ukraine	UKR
France	FRA	Montenegro	MRO	United Kingdom	GBR

**Note:** Monaco, San Marino, Kazakhstan and Montenegro have been excluded from the study due to lack of reliable data. It should also be noted that the Vatican is included in the statistics for Italy and Kosovo included in the statistics of Serbia for all the data from the World Press Trends 2007 (for which specific data available for the respective countries, see appendix I).

Lithuania, Luxembourg, Malta, Netherlands, Norway, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden, Switzerland, Turkey and United Kingdom.

It is of course possible to discuss what different operationalizations actually measure, and how comparable the operationalizations are between different countries. Problems of this nature are probably more common for data on new media technologies in general, and the Internet and broadband in specific. For example, a majority of citizens in one country with no access to the Internet or a computer at home should not necessarily be the same as they in fact have no access to a computer or the Internet at all. It could rather mean that information from the Internet is retrieved by visiting Internet cafés, libraries, school or workplaces. Despite this, access to a computer and the Internet at home is likely to lead to a more frequent exposure to a wider range of information, both in terms of news and entertainment. What seems to be an observable fact does not always relate the same way, or concerns the same thing in all contexts. It is therefore important to use various operational indicators of what is being investigated, and thus capture different dimensions of the same phenomenon. As far as more specific dimensions and definitions, such as what people are considered adults, or whether the definition of the indicator used is the same for all countries studied, are the requirement of awareness, and to examine specific dimensions. One approach is simply not to use questionable and dubious indicators and definitions for measuring a phenomenon, and that when in use, account for exceptions and differences, as mentioned earlier.

In this paper, method and design for implementation of comparisons - 'most equal' and 'most different' design the groups with similar characteristics can be the basis for a typology that in turn can be used to systematize a phenomenon (Esaiasson et al 2003, 110ff). It could for example be the case of differences between independent and state-controlled media structures or between commercial and public service television. In this case, it is a question of examining newspapers, television and the Internet, and based on relatively simple measure, to compare the differences and similarities in media systems, the inhabitants' accessibility to different media and how the consumption of media in practice is manifested. Based on these specific and relatively simple characteristics it is then feasible to in detail explain and compare countries 'media systems and to provide knowledge about the relationship between countries' media systems and political systems.

#### PART II: RESULTS

Before the results are presented and analyzed, I would very briefly like to explain how this paper's findings, technically speaking, have been developed.

Fundamentally, all results are presented using fields with two dimensions in which the factors studied are presented in pairs based on a simple coordinate system. The values presented for the countries (and each country's positioning at each axis) are based on the dimensions of each specific variable. The value of the specific factor is reduced (subtracted) with the average for all countries. As a consequence, the countries then can be ranked relative to one another from the highest to the lowest value. Since the limits of what is high or low is not expressed, the countries are positioned only on the basis of how they are related. The point with this approach is that factors or variables can be compared in pairs, and that countries can be studied from two dimensions at a time. Each figure is also supplemented with a R² value showing the percentage of explained variance for the dimensions studied, the proportion of the variation in y which can be explained by variations in x. Apart from this very simple data processing, the country-specific measurements are presented continuously in the text as well, which is entirely based on secondary data gathered from each source, which is compiled in tabular form in Appendix II.

To clarify the approach, here's an example: Let's say we want to compare Sweden, Estonia and Albania on the basis of 'Newspaper Circulation' (y) in relation to 'Urban Population' (x). Sweden has a newspaper circulation per 1,000 adults at 466.2, Estonia 241.7 and Albania 24.1. The average of the countries is 244. Each country's newspaper circulation is then subtracted with the mean (Sweden: 466.2-244=222.2; Estonia: 241.7-244=-2.3, and Albania: 24.1-244=-219.9). The same procedure is done for the countries' share of urban population: Sweden has an urbanization rate of 84 percent, 71 percent in Estonia and Albania to 35 per cent. The average share of urbanization is 63.3. Each country's urbanization rate is subtracted with the mean (Sweden: 84-63.3=20.7; Estonia: 71-63.3=7.7; and Albania: 35-63.3=-28.3). In this way, each country got a value equal the newspaper circulation (x) and a value for the share of urban population (y). These values can then be used to study and compare how countries are positioned in relation to each other. In addition to this, the R² value .45 indicates that 45 percent of the variation in the newspaper circulation (y) can be explained by variations in the share of urban population (x). Let us now turn to the results of this study.

#### 4. Media Structures in Europe

#### 4.1 Ownership

The differences in newspaper ownership are very clear. Few countries in Eastern Europe with a varying proportion of state-owned newspapers and the remaining European countries where state ownership not includes any newspapers at all (see Table A10 on page 57-58). *State* ownership is the term used for the proportion of the sum of the five

largest companies that can be traced to the government. The values indicate the proportion of companies controlled by the state and have been derived from data and definition in Djankov, McLiesh, Nenova, and Shleifers *Who Owns the Media* (2003).

Among Eastern European countries, Belarus was in 2003, at the top with state ownership of nearly all Belarusian newspapers. Nowadays, however, newspaper market has also opened up for private actors, but nevertheless the state-owned newspapers still account for as much as 85 percent of the Belarusian newspaper edition. An evidence is that the state shut down a number of independent newspapers as late as in the Belarusian presidential elections in March 2006. After Belarus there is a gap to the next country, Croatia where state ownership of newspapers is at 29 percent. Compared to Belarus, Croatia has developed in the opposite direction and the Croatian constitution guarantees freedom of expression and press freedom. In Armenia, every third newspaper is owned by the state. In Russia and Ukraine, the state owns almost a fifth of the daily newspapers, followed by Moldova (12 percent), Azerbaijan (10 percent), and finally Georgia with a state ownership at 6 percent.

Regarding television and state ownership of television channels, the public service model contributes to a significant impact on the figures on state television ownership broadly across Europe (see Table A10 on page 49-50 and Table A6a and A6b on page 41-42). In Belarus, Croatia and Russia, the state owns practically all television. Again, Croatia is an example of a country with an extensive state ownership. The leading Croatian television is part of the state-owned *Hrvatska Radio-Televizija (HRT)*, but there is also a television market that is open to private actors. After Croatia, we find Switzerland and Denmark, where state ownership is four fifths of the market. In Turkey, state ownership is almost non-existent and this applies also to Greece, where state ownership is one tenth of the total market. Interesting to note is the figures for Ukraine and Hungary (14 and 20 percent) are among the lowest in all of Europe.

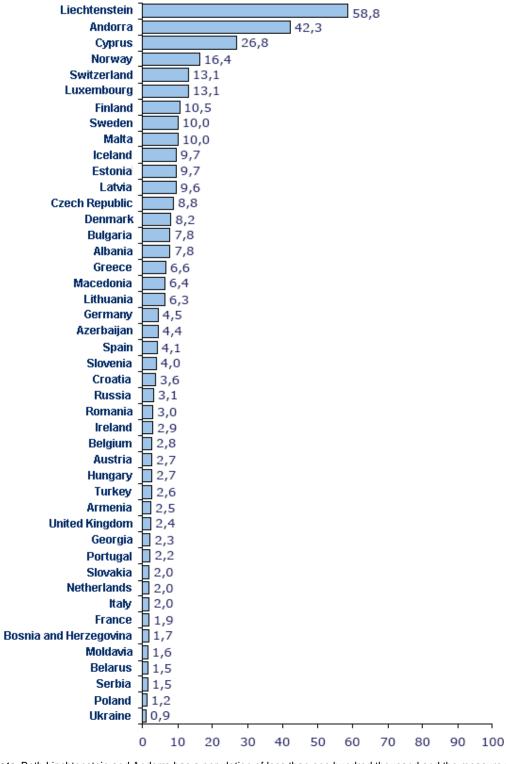

Regarding the daily press, a brief summary of the ownership structure of European countries shows that there is a clear difference between a few Eastern European countries with heavily state-controlled newspapers and other European countries where newspapers are more independent from the state. At the same time, we can see that some of the countries with a relatively high proportion of state-owned newspapers, but a trend towards increased democratization, strive towards a freer and more independent newspaper market. Regarding television and state-ownership of television companies and television channels, the public-service model contributes to a proportion of state ownership which is much broader than what is the case for the newspapers. If we put aside an almost total state control of television in Belarus, the share of state-owned television differs not so much between Belarus, Croatia, Switzerland and Denmark, but there are large differences between countries if we look at what the public service model means for the independence of the media vis-à-vis those in power.

# 4.2 The Newspaper Market

In 2006 there were around 2900 newspapers with a combined circulation of approximately 126 million copies in the European newspaper market. Compared with statistics from 2002, both the number of newspapers and the total circulation, has increased by almost 12 percentage points (see Table A1 on page 35). In Western Europe, the number of newspapers has been fairly stable in recent years. In Eastern Europe, on the other hand, there have been great changes in the newspaper market. Russia recorded a sharp rise from 436 titles in 2002 to over 552 in 2006, while Ukraine reported a decline from 76 titles in 2003 to 41 in 2006. The size of the newspaper market in part reflects the size of the countries. The largest newspaper market in Europe is the German market. In Germany, over 21 million copies is distributed per release day, making it significantly larger than the second largest market, Britain, with around 18 million copies per release. Germany and Britain also publish the two largest newspapers in Europe in terms of circulation: Bild (3.7 million) and The Sun (3.1 million). Large countries, but with relatively small newspaper markets, are Italy (about 10.3 million) and France (about 9.3 million). The Eastern European countries are also reporting relatively low circulation numbers. Poland has the largest newspaper circulation with about 5.7 million copies, an increase of almost 2 million copies since 2002. The Swedish newspaper market, with a circulation of about 4.7 million copies, is together with the Netherlands, the eighth largest in Europe.

If we specifically study the countries newspaper market, it is the total number of newspapers in relation to its population, which tells us most in terms of newspaper size and scope. A large country has virtually by definition, a major newspaper market and tells us relatively little about the scope of the daily press, while this type of measure also reflects how local the newspapers are in different countries - many newspapers indicates a high proportion of local/regional newspapers and few newspapers indicates a high proportion of national newspapers. The total number of newspapers here refers to the total number of newspapers with a release of at least four times a week (for more information about the distribution between newspapers and free newspapers, see Figure A1 on page 36). In Figure 1, the countries are ranked by the total number of newspapers per one million inhabitants for each country in 2006.

**Note:** Both Liechtenstein and Andorra has a population of less than one hundred thousand and the measure will therefore be misleading for these two cases.

Source: World Press Trends 2007.

The countries at the top have a small number of newspapers distributed on a relatively small population. Liechtenstein and Andorra have two and three newspapers on a total population of approximately 34,000 inhabitants in Liechtenstein, and approximately 71,000 inhabitants Andorra. Cyprus has 21 newspapers and a population of approximately 784,000 inhabitants (see Table A1 on page 35 and Table A3 on page 38). The newspapers are distributed roughly equally between Greek and Turkish Cypriot newspapers. Seven of the eight major Greek newspapers are Greek-speaking, and one is English: *Phileleftheros* is the largest paper with a circulation of about 250000 copies, and it is accompanied by *Politis*. On the Turkish Cypriot side are *Sabah* and *Hurriyet* from the Turkish mainland the largest with a newspaper circulation of around 13,000 copies while the most popular Turkish Cypriot newspaper *Kibris* never reach over a circulation of 10000 copies per day.

Norway is the country in the north with the greatest number of newspapers in relation to its population, and the figure on newspaper reading is one of the highest throughout the world (about 600 newspapers per 1,000 adults). All Norwegian citizens in virtually all segments, both geographically and socially, are regular newspaper readers. The Norwegian newspaper market is dominated mainly by two national newspapers, *Verdens Gang (VG)* with a circulation of about 334,000 newspapers and *Dagbladet* of about 162,000 newspapers. The interesting thing about these two newspapers is that they are purchased as single copies.

Among the countries with a low number of newspapers in relation to its population, Ukraine is the country with the lowest number of newspapers followed by Poland. The Polish newspaper market is dominated by foreign and mainly German owners but has one large domestic actor (Agora SA). *Gazeta Wyborcza*, which started in 1989 and is owned by Agora SA, was the first independent newspaper after the communism. Gazeta Wyborcza was the biggest Polish newspaper for nearly a decade; around 1999, *Fakt* took over the top position.

In Belarus, 15 newspapers are distributed on a population of approximately 9.8 million inhabitants, according to the *Belarusian Association of Journalists*, there are approximately 30 privately-owned political newspapers in the Belarusian newspaper market. The opportunities now available for private actors to operate on the Belarusian newspaper market do not mean that private newspapers are run on under the same conditions as the state-owned newspapers. Half of all privately owned newspapers are completely excluded from the established distribution networks while the Belarusian State finances the distribution of state-owned newspapers.

#### 4.3 The Television Market

It is clear that the European television market differs between European countries when compared on the basis of the total number of channels (see Table A6A and A6b on page 41-42). Total number of channels refers to all television channels that exist in the television markets, and therefore also covers a wide range of foreign operators. IP

International Key Facts sort the channels into four categories: *Domestic Public Channels*; *Domestic Private Channels*; *Pan European and Other Foreign Channels* and finally *Premium Pay TV Channels*. This is also the classification used in this paper.

The television market, which by far has the largest total number of channels, is the Polish (148 channels), followed by France (123 channels). With 91 channels, Germany comes as number three, and Iceland is number four with 67 channels. Croatia has a minimum number of channels, four channels; slightly more has Cyprus with seven channels. If we look to all countries, the number of television channels the figures varies between approximately 20 to 40. This must also be taken into account when looking at Figure 2, where the relationship between the total number of channels and size is out mapped.

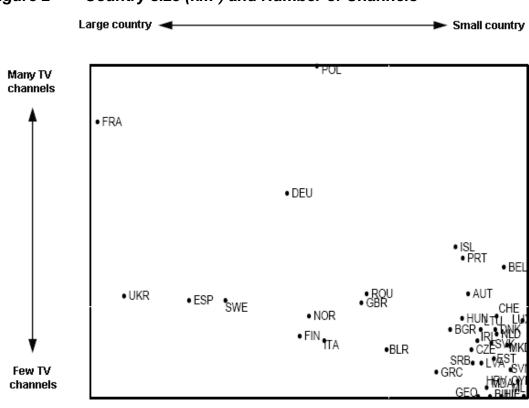

Figure 2 Country size (km²) and Number of Channels

**Note:** The following countries are not included in the figure due lack of data: Albania, Andorra, Armenia, Azerbaijan and Russia. For identification of the country alpha codes see Table 1 on page 8. R² shows that 1 percent of the variation in the number of channels can be explained by variations in their size.

Source: IP International Key Facts 2007 and CIA World Factbook 2007th

Based on the dimensions of size and the number of channels, the countries with the smallest area also tend to have a smaller number of television channels. Since Russia is not included in the figure, the two largest countries are France and Ukraine. The differences between these two countries also show that differences in the number of channels depend on other factors than just the specific country's size in terms of square

miles. The state television monopoly in France ceased in the late 1980s, and since then the number of channels has increased, especially in terms of local and topic-specific channels. In 1980 there were three television channels in France, while today, in addition to the seven terrestrial channels, there are hundreds. It is also worth noting that the public-service channels, despite the increased choice of channels, still have the largest share of the French audience (total of 89 per cent).

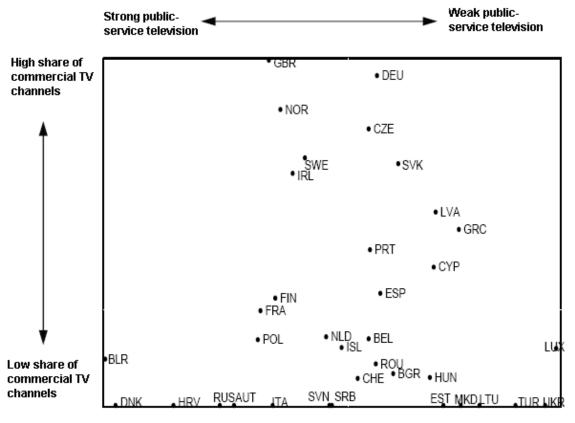

If we divide the total number of channels in the categories Domestic Public Channels, Domestic Private Channels, Pan European and Other Foreign Channels, and Premium Pay TV Channels, the countries that are placed in the top in the category of Domestic Public Channels, Spain (with 22 channels) followed by Germany and Poland (with 17 channels) each. Lowest numbers of Domestic Public Channels have the countries of Estonia, Luxembourg, Ukraine and Iceland, with one channel each.

Concerning the share of Pan European and Other Foreign Channels, Iceland is at the top (84 percent of the total number of channels), followed by Luxembourg (79 percent of the total number of channels). In contrast, Croatia, Czech Republic, Greece, Serbia, Slovenia, Turkey and Hungary have the lowest proportion of foreign channels.

For the private television market and the proportion of Domestic Private Channels, Hungary is in the top with 89 percent of the total number of channels. France holds second place with 78 percent, and as number three we find Turkey, with 74 percent. Turkey is an interesting example of how the range of channels increased alongside a state monopoly. The first Turkish radio and television broadcaster *TRT* was started by the Turkish state in the mid-1960s and held the broadcasting monopoly in almost two decades. Then, when the first private television channel *STAR 1* started broadcasting via satellite from Germany in 1990, this contributed to a significant increase in private channels, which in turn meant that the Turkish state broadcasting monopoly dismantled in mid-1990s.

The example of Turkey shows an interesting dimension of the relationship between the relationship between the share for public-service and state-owned television channels in relation to the share of commercial channels. A country with relatively weak public service can be expected to offset this with a relatively high number of commercial TV channels and vice versa. Based on Figure 3, this is most evident among the countries where public-service is strong and the share of commercial television channels is relatively low.

Figure 3 Public-service and Commercial Television Channels Audience Shares (percent)

 $R^2 = .33$ 

**Note:** The following countries are not included in the figure due lack of data: Albania, Andorra, Armenia, Azerbaijan, Bosnia and Herzegovina, Georgia, Liechtenstein, Malta and Moldova. R<sup>2</sup> shows that 33 percent of the variation in the proportion of Commercial TV channels can be explained by variations in the strength of Public Service television. **Source:** IP International Key Facts 2007

Based on the public-service dimension, Denmark (70 percent) and Ukraine (0 percent) are opposed to each other in the same way as Britain (36 percent) and Italy (0 percent) are on the basis of the proportion of commercial television channels. Denmark has a low share of commercial channels and a strong public-service tradition. The lack of access to frequencies in the terrestrial network strongly contributed to the privileged position of two public service broadcasters, *DR* and *TV2*. Since 2009, however, the digitalization of the Danish TV network has changed the situation considerably.

Italy, like Denmark, has a low share of commercial television channels, whereas the share and the strength of public-service television, on the contrary, is significantly weaker. In Italy, the Italian television audience is in the situation to choose between eight free national and approximately 800 local television channels. At the same time the broadcasters *RAI* and *Mediaset* control about 85 percent of the Italian television market, a fact something that also has implications for the audience share of the public-service

channels. Interacting cases are Ukraine and Turkey, with a weak public-service television but relatively few commercial television channels.

Of the countries where statistics are available, the state-owned television channels have an audience share of 71 percent in Belarus, compared with, for example, Russia where the state or publicly owned television channels and television companies together represent 54 percent of the audience share. The largest Russian national channel is public service channel *ORT*, which reaches 98 percent of the Russian people (approximately 140 million viewers). The television channel *Russia* is the second largest with an audience reach of 98.5 percent (and approximately 50 million viewers). The weakest position of the public-service channels is found in Luxembourg and Ukraine (1.3 and 3.0 percent respectively).

To summarize, the European television market is a far more complex media market than the European newspaper market in the sense that countries' range of channels tend to overlap and reach beyond country borders more widely than for example the case of the European newspapers. This contributes to difficulties when, for example, defining a specific country's choice of channels.

As mentioned initially, the public-service model is very important for how the country-specific range of channels looks like. Apart from the Polish, French and German television channels, the countries of Europe remains relatively divided in amount of television channels, which include structural factors such as the possibility of establishment, broadcasting, access to broadcast frequencies and with digitalization play an important and decisive role in the number of channels included in national television range.

# **4.4 The Advertising Market**

When we want to measure and compare the effectiveness of specific media, the advertising market is probably the indicator that best measures the strength of specific media in a country. It is likely, for example, to expect that media that have a large share of the advertising market also reach out to a large audience, and vice versa. Figure 4 shows the specific media's share of total advertising market in each country. The category 'Other' consists of advertising shares in magazine, cinema and outdoor advertising.

If we start by looking at the countries where advertising in newspapers represent the largest proportion of the total advertising market, Ireland is in the very top (see Table A9a on page 45). The advertising in newspapers represents 60 percent of the Irish advertising market. Also in Finland are newspapers strong in the advertising market (53 percent). If we then look at the countries where the press has a small percentage of the total advertising market, the newspapers advertising share is lowest in Ukraine (5 percent), closely followed by Slovakia (6 percent), Bosnia and Herzegovina (7 percent), Portugal (8 percent) as well as Romania and Hungary (9 and 10 per cent).

In Bosnia and Herzegovina, it is instead the advertising on television that dominates, and it has risen from 65 percent in 2002 to 90 percent of the total advertising market in 2006. This can be compared with Ukraine, where the advertising share of television has fallen by 23 percentage points over the same period (see Table A9b on page 46). Countries where the share of television advertising is lowest is Finland, Ireland and Denmark (20 percent each), Sweden and Switzerland (23 percent) and Germany and Austria (24 percent).

Ukraine Greece 15 France 36 Switzerland 56 Portugal 8 Germany 40 24 39 24 Austria Netherlands 25 Czech Republic 19 16 Poland **United Kingdom** 34 14 Latvia 28 12 26 39 Belgium 53 **Finland** Romania Spain 25 Russia 25 Sweden 45 Italy 19 55 Hungary Slovenia 21 55 Croatia 14 68 Estonia 43 Bulgaria 67 Norway 42 27 5 60 20 Ireland Slovakia Lithuaina 72 Turkey 31 57 3 Bosnia and Herzegovina 50 30 40 60 70 80 90 10 20 100 Dailies ■ Radio □ Internet ■ Other

Figure 4 Advertising Market Shares of different Media (percent)

**Note:** Data for Denmark does not add up to one hundred percent and have therefore been excluded from the figure. 'Other' consists of advertising shares in magazine, cinema and outdoor advertising and has been merged into a single category.

Source: World Press Trends 2007.

For advertising on the Internet, United Kingdom is at the top (14 percent of the total advertising market), followed by Sweden and Norway (11 percent) (see Table A9d on page 48). This means that United Kingdom and Norway caught up with Sweden since 2002.

Ukraine is the only country where the development of Internet advertising in the advertising market, albeit very marginally, has declined since 2002 (-0.5 percent).

Another phenomenon that is interesting to note is that the 'Other' category represents as much as half of the total advertising market in both Ukraine and Greece (61 and 49 per cent), and that all media but outdoor advertising had a negative development on the Ukrainian advertising market, if we compare with the statistics from 2002.

To summarize the comparisons we have made, we see trends where the shares of advertising on the Internet is highest among the Western European countries, while the share of television advertising is the largest among the Eastern European and some individual countries of Southern Europe.

# 5. Media Consumption

In the previous section we compared the media structure in different European countries. We also compared the strength of different media and came to the conclusion that the press is strongest in the North and the Western European countries, while television has the greatest impact in former communist countries, and in some individual countries of Southern Europe. However, the strength of different media is also based on the extent to which the audience actually takes part of it - the public's consumption (exposure), the media consumption in different countries is studied in this section, starting with the consumption of newspapers.

#### **5.1 Newspapers**

One of the biggest differences between countries' media systems is linked to the development of mass-distributed newspapers. In some countries, the daily press was established and developed in the late 1800s, in others it was not. Hallin and Mancini show that these historical differences are reflected by large current differences in newspaper circulation. To compare media consumption, I have chosen to compare the figures on each country's average newspapers circulation per 1,000 adults.

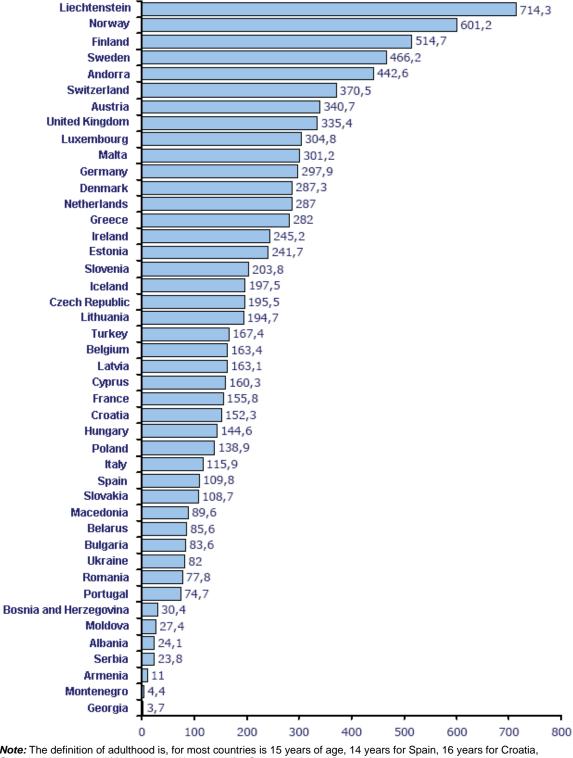

For European countries, the differences in the newspaper circulation are relatively large. In Figure 5, there is, albeit with some exceptions, a fairly clear dividing line between Northern, Southern European and former communist countries in the Eastern Europe. At the top we find Liechtenstein, Norway, Finland and Sweden and in the bottom, we find Georgia, Armenia, Serbia and Albania. If we compare the figures in Figure 5 with those

of earlier years, we can see that the average newspaper circulation is relatively stable (see Table A1 on page 35).

Spain has had the most positive development of the newspaper circulation since 2002 with an increase of approximately 373 newspapers or approximately 3.7 million copies. Other countries that also had a positive trend are Ukraine (about 351 newspapers), Poland (about 187 newspapers), Turkey (about 180 newspapers) and Russia (about 114 newspapers). Among the countries that had a negative development for the newspaper circulation, Germany has experienced the biggest decline (about -201 newspapers or approximately 2 million copies) and United Kingdom is marked with the second largest reduction (about -74 newspapers). The general trend of newspaper circulation since 2002 and for Europe as a whole is that the development of the Western European countries is negative, while the circulation in Southern and Eastern Europe is increasing, which can be traced to the establishment of free newspapers.

The conditions for a newspaper expansion have differed greatly between different countries, and this has meant that the newspaper market has developed differently in different parts of Europe. One country that had a relatively widespread daily press early was, for example United Kingdom. In other countries, such as the Scandinavian, the expansion came later but was nevertheless very strong. In Southern Europe, the newspapers never reached mass-distribution, except in certain limited regions, partly because of lower degrees of urbanization.

Something that is important to emphasize is that the differences here outlined also tell us something about the perception of newspapers, the relationship with the audience and the newspaper's role in the social and political communication process in different countries. In Southern Europe for example, newspapers are addressed and read primarily by a small clearly defined well-educated, urbanized and politically active elite. In the Nordic countries, on the contrary, newspapers are intended for a wide audience, not necessarily interested or involved in the political life. There are also obvious historical differences. Newspapers in the former communist countries have been subsidized and supported by political actors and do not have a history of being for-profit companies, while the Northern European countries have a strong tradition of newspapers as businesses run for profit.

Average Newspaper Circulation per 1,000 Adults (number) Figure 5

Note: The definition of adulthood is, for most countries is 15 years of age, 14 years for Spain, 16 years for Croatia, Georgia, Lithuania and Macedonia, and 18 years for Greece, Italy and Portugal.

Source: World Press Trends 2007.

If we compare countries based on the average newspaper circulation per 1,000 adults and degree of urbanization, there are differences in the circulation that can be linked back to how the newspaper market has developed, but no clear and general pattern can be identified based on the urbanization dimension (see Table A3 on page 38).

Figure 6 Newspapers Circulation and Urban Population (percent) High degree of Low degree of urbanization urbanization NOR High circulation FIN SWE CHE AUT GRC EST IRL ISL BEL ESP PR Low circulation ARM R2= .17

Note: The following countries are not included in the figure due lack of data: Andorra, Azerbaijan, Bosnia and Herzegovina, Liechtenstein, Serbia and Slovakia. R<sup>2</sup> shows that 17 percent of the variation in the daily newspapers circulation can be explained by variations in the degree of urbanization. Source: World Press Trends 2007 and The Quality of Government Institute 2007.

Belgium has the highest degree of urbanization but is relatively low in terms of average circulation (163.4 copies per 1,000 adults). The same goes for Iceland, with an urbanization rate of 91 percent and an average of 197.5 copies per 1,000 adults. Portugal and Albania have the lowest degrees of urbanization, where about two-thirds of the total population lives in rural areas.

The next thing to do is to ask whether the newspaper markets consist of national or regional/local newspapers. The Belgian newspaper market is well balanced with the share of local newspapers roughly as big as that of national newspapers. On the Icelandic

market, on the other hand, there are only a few large national newspapers, while for example the Swedish and the British newspaper markets consist of a few large national and numerous regional/local newspapers (see Table A5 on page 40).

Another factor affecting the public's consumption and average newspaper circulation is the national economy. The measure used here is GDP per capita by purchasing power parity (PPP) and shows the total value of a country's total consumption of products and services, the value of gross investment and the value of exports minus imports divided by the country's total population. PPP also takes more factors into account than the exchange rate, such as inflation and cost of living (see Table A9a on page 45). One can, for example, imagine that the newspaper circulation is higher in a country with high GDP per capita and lower in a country with low per capita GDP. On the other hand, factors like population, the total number of newspapers and whether the newspaper market consists of many small or a few major actors plays a key determinant of how large the newspaper circulation eventually becomes.

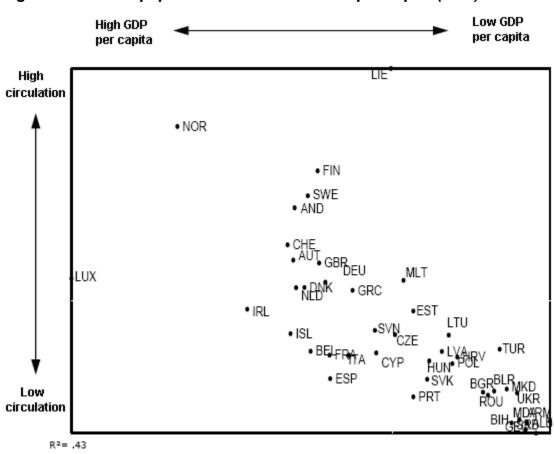

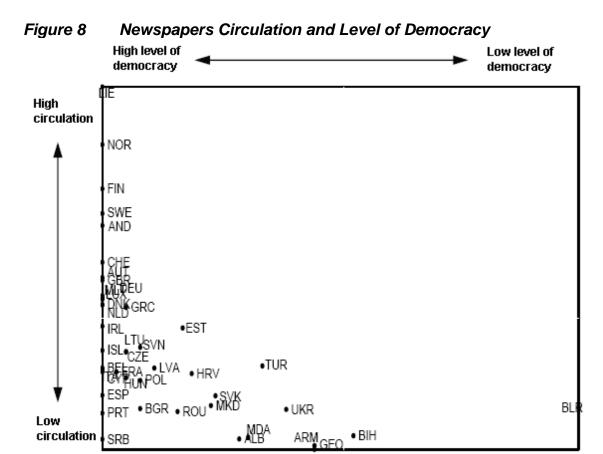

Figure 7 Newspapers Circulation and GDP per capita (PPP)

**Note:** The following countries are not included in the figure due lack of data: Azerbaijan and Russia. R² shows that 43 percent of the variation in the daily press circulation can be explained by variations in GDP per capita. **Source:** World Press Trends 2007, World Development Indicators 2007.

In Figure 7 we can see that the relationship between newspaper circulation and GDP per capita vary. Luxembourg for example, has a relatively small average newspaper circulation in relation to its economy, partly because of a very small population (approximately 34,000 inhabitants) and partly because of a newspaper market that consists of only a few actors. Norway is marked by economic prosperity and a "high" newspaper circulation. The Norwegian newspaper market consists of 77 newspapers (8 national and 69 regional/local) and the figures are roughly the same for neighboring countries such as Sweden and Finland. In 2008, the Swedish newspaper market consisted of 91 daily newspapers distributed on four national, 81 regional/local, and six free newspapers. The Finnish newspaper market consisted in the same year of 55 newspapers distributed among nine national, 44 regional/local and two free newspapers. If we look at the countries that differ from this pattern, we can see that, for example Ireland, with a high GDP per capita has a relatively low newspaper circulation and a newspaper market that consists of twelve newspapers (distributed in eight national, one regional/local and three free newspapers). Also Iceland has had a high GDP per capita, and despite this a relatively low number of newspapers (3 pieces).

Another factor affecting the number of actors in the newspaper market is the degree of democracy and opportunity to establish on the countries newspaper markets. The measure used comes from Freedom House and is an index based on the freedom of opinion and assembly, as well as opportunities to participate in the political process (vote, compete in elections, to join political parties and organizations). The scale ranges from 0-10 where 0 is least democratic and 10 most democratic.

What is perhaps most clearly in Figure 8 is that the variation in the degree of democracy, as expected, is relatively low among European countries, but at the same time, there are some variations. Andorra, Austria, Belgium, Cyprus, Denmark, Finland, Germany, Iceland, Ireland, Italy, Liechtenstein, Luxembourg, Malta, Netherlands, Norway, Portugal, Switzerland, Slovenia, Spain, and Sweden has value 10.0 on the democracy scale, and are considered well-established democracies. But Europe also includes countries like Belarus and Azerbaijan, who is placed far down on the democracy scale (1.58 and 2.0), with a relatively large gap to the third lowest country Bosnia and Herzegovina with a democracy level of 5.56. The established democracies cover the whole range from small to large newspapers circulation; as we have seen previously, in many cases, the circulation degree depends on other factors than the degree of democracy. At the same time, we can see that there are some less established democracies, regardless of size, etc., that stand out in having high newspapers circulation, which nonetheless suggest that the country's democracy level has relevance in some specific cases.

**Note:** The measure used comes from Freedom House and is an index that shows the freedom of opinion and assembly, as well as opportunities to participate in the political process (vote, compete in elections, to join political parties and organizations), the scale ranges from 0-10 where 0 is least democratic and 10 most democratic. The following countries are not included in the figure due lack of data: Azerbaijan and Russia. R² shows that 26 percent of the variation in the daily newspapers circulation can be explained by variations in the degree of democracy. **Source:** World Press Trends 2007 and the Freedom House/Imputed Polity 2004.

## 5.2 Television

 $R^2 = .26$ 

In the case of television we can see that the consumption of television has spread widely over all the European countries (see Table A6A and A6b on page 41-42). In Cyprus, all households are counted as "TV households" with access to at least one television set. In Slovenia, the share of TV households is at 99.6 percent, and for Portugal and Spain it is at 99.5 percent. Slovakia has the lowest percentage of TV households with 84.8 percent of all households, followed by Germany (86.6 percent), Greece (90.2 percent), Ukraine (90.7 percent) and Finland (91.4 percent).

If we then compare the time individuals spend in front of their television sets, Serbia is located at the top with a viewing time at 285 minutes per day, while the people in Belarus and Iceland, which has the lowest consumption in terms of minutes per day; just spend 154 minutes in front of the television per day.

How are countries positioned relative to one another if we compare the average viewing time per individual per day in relation to the audience share for public-service television? In Figure 9 we can see that the two countries, that are highest in audience shares for the public-service or state/publicly owned television also are the countries that have relatively short individual viewing time (in minutes) per day. Belarus and Denmark have the highest audience shares for public-service and state/publicly owned television but relatively low viewing time, something that also applies for the neighboring Nordic countries.

Figure 9 Viewing Time per Individual mon-sun (minutes) and Audience Shares for Public Service and Commercial Television (percent)

**Note:** Data for audience shares are from 2004. The following countries are not included in the figure due lack of data: Albania, Andorra, Armenia, Azerbaijan, Bosnia and Herzegovina, Georgia, Liechtenstein, Malta and Moldova. R² shows that 3 percent of the variation in viewing time can be explained by variations in audience share for public service television.

Source: IP International Key Facts 2007.

Finland, Norway, Sweden and Iceland, together with Switzerland, Belgium and Luxembourg have relatively low viewing time per individual. If we instead look at countries with high levels of individual viewing per day, we see with the exception of Croatia and Serbia, that they also have high audience shares for the commercial television. In Hungary, the average Hungarian spends 279 minutes watching television per day, 274 minutes in Macedonia, and Greece 263 minutes per individual and day.

#### **5.3** Internet

In addition to traditional media, I have also chosen to complete the picture of the European media systems with new media, in this case the Internet and the development of and access to broadband. Internet use and, broadband access tell us something about to what extent different information is available for the audience, but also on the development and interaction between traditional media and new technologies, as well as the diversity and range - the access the European citizens, in practice, have to various and alternative information and news sources.

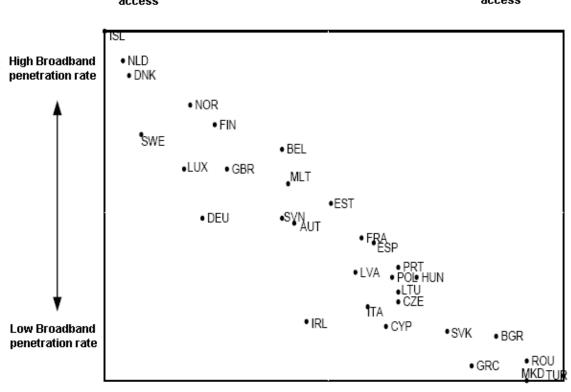

We have previously discussed what the different dimensions actually measure and that the fact that the majority of the citizens of a country have no access to the Internet at home not necessarily means that they have no access to the Internet at all. At the same time, the access to a computer and the Internet at home means that the exposure becomes more frequent and that the media supply is increased, both in terms of news and information. It is also much more difficult for authoritarian and totalitarian states to control and manage the information that citizens receive, whereas it requires some technological conditions for the citizens to be able to take advantage of the increased flow of information offered via the Internet.

Figure 10 shows very clearly, and perhaps not very surprisingly, that access to the Internet and the broadband penetration rate are closely interrelated. Among the countries where a large proportion of the population has access to the Internet, the proportion of households with access to broadband is also relatively high. In Iceland, approximately 91 percent of households have access to a computer of some kind. 83 percent of the Icelandic people have access to Internet, and 72 percent of Icelandic households have broadband access (see Table A7 on page 43). It is also Iceland that has the highest percentage of the population who regularly use the Internet. The Netherlands ranks second in terms of access to the Internet and broadband penetration rate, but is lower in terms of access to computers than, for example, Sweden and Denmark (the Netherlands 72 percent, Denmark 84 percent). This is also the case with regard to the share of individuals who regularly use the Internet (the Netherlands 76 percent, Sweden 78 percent).

Figure 10 Internet Access and Broadband Penetration Rate (percent)

High Internet access

Low Internet access

 $R^2 = .87$ 

**Note:** The share of households with access to Internet is based on all citizens between 16-74 year of age and the share of households with access to broadband include households with at least one person aged 16-74 years. The following countries are not included in the figure due lack of data: Albania, Andorra, Armenia, Azerbaijan, Belarus, Bosnia and Herzegovina, Croatia, Georgia, Liechtenstein, Moldova, Russia, Serbia, Switzerland and Ukraine. R² shows that 87 percent of the variation in access to broadband could be explained by variations in access to Internet. **Source:** Eurostat 2007.

Norway is a country where access to a computer is higher than, for example, Sweden and Denmark (85 percent), but where Internet access is lower (69 percent in Norway and 77 percent in Sweden). Sweden is high, both in terms of access to computers, Internet access and regular Internet usage in comparison with its Nordic neighbors, but lower with regard to access to broadband (51 percent). Nevertheless it should be noted that there are only six European countries where over half of the households have Internet access via broadband, and only 14 countries where over half of the households have Internet access at all, the majority of countries are marked by figures that are significantly lower.

If we look at countries with low Internet and broadband access, it would have been really exciting if there were reliable data for countries such as Azerbaijan, Belarus, Bosnia and Herzegovina, Georgia, Croatia, Moldova, Russia, Serbia and Ukraine, to see if they end up high or low in relation/when compared with the other countries. Instead, we can note that Turkey is the lowest of all countries, in terms of access to the Internet, and the second lowest with regard to the share of households with broadband access (in

Macedonia, one percent of all households have access to broadband). In Turkey, about 23 percent of the households have access to a computer of some kind. Eight percent of the Turkish population has access to the Internet, two percent of the Turkish households have access to broadband and 12 percent of the population uses the Internet regularly.

If we instead take a look at other forms of access to Internet it is still Turkey together with Bulgaria that are marked by lowest figures of access. Germany and Ireland where about 35 percent of Internet use is via telephone modem/ISDN are in the top, followed by Sweden and Luxembourg (25 percent each).

There are large differences between the European countries, both in terms of access to the Internet in general and more specifically with regard to broadband. It is likely that these differences are, due to factors such as urbanization, infrastructure and whether economic development is positive or negative. Perhaps it is somewhat surprisingly, France and Germany have not progressed very far in access to the Internet and broadband.

# 6. Media Systems in Europe

Based on the four ideal models that Hallin and Mancini identified on the relationship between media systems and political systems, the comparisons between the European countries based on dimensions of structure, access and consumption, show that the patterns Hallin and Mancini argue as typical for the four ideal models, albeit with some exceptions, are actually confirmed. This is most clearly reflected when we compare countries based on media structure and newspapers markets, but it is also noticeable when we study and compare patterns of use and consumption. Although we can see that there are relatively large variations between countries in the ideal models and the factors studied, even if these tend to be smaller. The differences that can be identified with regard to newspaper reading derive from historical differences. But at the same time, we can see a clear tendency for those countries that did not develop mass-distributed newspapers in the late 1800's to catch up with those that did, and this regardless of whether the levels of literacy, political and economic development are the same as for countries with large newspapers circulation.

Background and history, for example in the development of newspapers and television, can not change, but it is clear that its meaning evolve to become less and less important. This lack of importance is due both to increasing internationalization of ownership and ownership structures, and the fact that democracy is becoming more established and widespread.

Another reason for the differences between European countries media systems is decreasing, and further, that the variation between countries in the different ideal models are becoming less clear is that democracy is becoming more established and widespread among the European countries in general, if as yet in varying degree and scale. If we for example look at the countries within each ideal model one can see by far the largest variation between countries within the The Post-Communist Media Model. Although,

there are examples of former communist countries, that have passed the South European countries, and in some cases even their Western European neighbors. This is most clearly defined over time and primarily among former Communist countries and countries in the Polarized Pluralist Media Model.

If we compare the former communist countries and the countries belonging to the Polarized Pluralist Media Model, we can see examples of several countries that quite easily could change places. Italy and France, for example, has significantly lower number of newspapers per 1 million inhabitants than Albania, Azerbaijan, Russia, Armenia and Georgia. Another example is the share of Internet advertising of the total advertising market, in which Greece and Ukraine follow approximately the same trend. Another example is when we compare the two ideal models based on the average newspaper circulation per 1,000 adults, where both Russia and Ukraine reach higher than, for example Portugal.

I am not arguing that my examples above provide evidence that countries consistently could switch between the ideal models presented by Hallin and Mancini, but rather that the limits and criteria for which countries are placed into each ideal model in some respects is diffuse. Due to an active striving towards a single European media system still formed, the overall variations within Europe is altogether likely to decrease – and this is holds true if comparisons are made between as well as within the ideal models.

**Note:** All data are from 2001. The variables show the probability that two randomly selected individuals from the same country belong to the same ethnic, linguistic or religious group. The higher the value the greater fractionalization. **Source:** World Press Trends 2007, The Quality of Government Institute 2007.

**Note:** Economic influence examines the economic environment for the media. This includes the structure of media ownership; transparency and concentration of ownership; the costs of establishing media as well as of production and distribution; the selective withholding of advertising or subsidies by the state or other actors; the impact of corruption and bribery on content; and the extent to which the economic situation in a country impacts the development of the media. <a href="Judicial influence">Judicial influence</a> encompasses an examination of both the laws and regulations that could influence media content and the government's inclination to use these laws and legal institutions to restrict the media's ability to operate. <a href="Political influence">Political influence</a> evaluates the degree of political control over the content of news media. Issues examined include the editorial independence of both state-owned and privately owned media; access to information and sources; official censorship and self-censorship. Scales ranging from 0 (less judicial and economic impact) to 30 (more judicial and economic impact) and 0 (less political influence) and 40 (more political influence). The press freedom scale ranging from 0 (least press freedom) to 100 (most press freedom). Market shares measure the state-owned newspapers and television share of respective country's five largest newspapers (circulation) and the five largest TV stations (viewers). \* Data are from 2003.

\*\*Source:\*\* Freedom House 2007 och The Quality of Government Institute 2007.
